Glossary

Random	Sample selection that ensures an unbiased representation of the research population
Non-random	Any other kind of sample selection than random, often convenience sampling
Exhaustive	Fully comprehensive sample of a population
Non-exhaustive	Sample of a population that does not include the entire population

Executive summary

Objectives

People with chronic HBV and/or HCV infection are at risk of serious liver disease such as liver cirrhosis and hepatocellular carcinoma (HCC) and remain infectious to others. Because chronic HBV and HCV infections are typically asymptomatic, notification data reflect national screening and testing practices and do not give accurate insights into the prevalence of infections. Thus, to adequately inform primary or secondary prevention efforts, supplementary information such as prevalence data are needed.

ECDC conducted a systematic review of the literature published between 2005–2015, with the aim to provide current estimates of the prevalence of HBV and HCV in the general population and specific population subgroups in the EU/EEA Member States, and to identify gaps in the available information. This review is an update of a previous systematic review covering the period 2000–2009.

Overview of methods

This systematic literature review was carried out to retrieve, assess and synthesise all available data published between 2005 and 2015 on the prevalence of hepatitis B and C in EU/EEA countries in the general population and the following subgroups: blood donors, pregnant women, people who inject drugs (PWID), men who have sex with men (MSM), prisoners and migrants.

A search strategy was developed and a literature search performed. Publications of interest were first screened based on title and abstract. The full text of all publications selected during the title and abstract screening was then assessed for relevance. This was followed by extracting the relevant data from the final selected publications. Data from each study were extracted using a predefined set of variables covering study characteristics, study population details, prevalence of HBV and HCV markers (HBsAg and anti-HCV antibodies), including the type of sample that was collected and the type of laboratory test that was used. Finally, the risk of bias was assessed for each study and used to categorise the included studies according to quality indicators defined in the study design.

To assess the prevalence of HBV and HCV among blood donors, PWID and migrants, alternative sources for data were used. These sources were the latest Council of Europe report on national blood donor data, data from the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) database and an ECDC systematic review entitled 'Epidemiological assessment of hepatitis B and C among migrants in the EU/EEA'.

An algorithm, which also took into account study quality, was used to develop a general population HBV and HCV prevalence estimate for each EU/EEA country, with the aim to estimate the current burden of chronic HBV and HCV in the EU/EEA.

Overview of the results

After a full-text screening, a total of 125 articles were considered for inclusion: 48 on the general population, 32 on pregnant women, 32 on prisoners, and 13 on MSM. In total, 211 prevalence data points were identified, ranging from 0 to 33 estimates per country.

For HBV, estimates that were considered representative for the **general population** in the risk of bias assessment were available for 13 countries, where the prevalence ranged from 0.1% in Ireland to 4.4% in Romania. For HCV, prevalence estimates that were considered representative for the general population were available for 13 countries, with the reported prevalence ranging from 0.1% (Belgium, Ireland and the Netherlands) to 5.9% (Italy).

High-quality estimates (according to the risk of bias assessment criteria) for HBV prevalence in **pregnant women** were available for seven countries, ranging from 0.1% in Norway and Spain to 0.8% in France and Italy. Of the 15 estimates identified for HCV prevalence among pregnant women, high-quality estimates were available for four countries with prevalence ranging from 0.1% in Slovenia to 0.9% in Norway.

Estimates from eligible studies for the HBV and HCV prevalence in **MSM** were available for four and six countries, respectively. For HBV, the prevalence in MSM ranged from 0.0% in Estonia and the United Kingdom to 1.4% in France. The prevalence of HCV among MSM ranged from 0.0% in Italy to 4.7% in Estonia.

HBV prevalence estimates that were considered representative for **prisoners** were available for 11 countries. HBV prevalence in prisoners ranged from 0.3% in Ireland to 25.2% in Bulgaria. HCV estimates that were considered representative were available for 11 countries, ranging from 4.9% in Hungary to 86.3% in Luxembourg.

The prevalence of HBV and HCV in **first-time blood donors** was available for 30 countries. The prevalence of HBV among first-time blood donors ranged from 0.0% in Finland and Luxembourg to 3.2% in Bulgaria. Most

countries (60%) had an HBV prevalence that was below or around 0.1%. The prevalence of HCV among first-time blood donors ranged from 0.0% in Iceland to 2.2% in Latvia, although the Latvian estimate is not very recent (2003). Around a third of the countries (32%) had an HCV prevalence that was higher than 1%.

National estimates on the prevalence of HBV in **PWID** were available for seven countries and ranged from 0.5% in Croatia, Hungary and Ireland to 6.3% in Portugal. National estimates for HCV in PWID were available for 16 countries and ranged from 13.8% in Malta to 84.3% in Portugal.

Estimates for the prevalence of HBV in the representative general **migrant population** were available for five countries. According to the available estimates, the prevalence of HBV in migrants varied by country or origin and ranged from 0.0% to 17.4%. The highest prevalence is reported among migrants from countries in south-east Asia, irrespective of their current country of residence. For three countries, Italy, the Netherlands and the United Kingdom, HCV estimates were available. The HCV prevalence in migrants ranged from 0.0% to 7.1%, with the highest prevalence reported among migrants from eastern Europe in Italy.

Based on general population and blood donor estimates, the HBV prevalence in the EU/EEA as a **whole** is estimated to be 0.9% (95% CI 0.7–1.2), corresponding to almost 4.7 million HBsAg-positive cases. For HCV, the estimated EU/EEA prevalence is 1.1% (95% CI 0.9–1.4), corresponding to around 5.6 million anti-HCV-positive cases.

Conclusions

This systematic literature review explores the prevalence of chronic HBV and HCV infections in EU/EEA countries. Studies with recent data on HBV/HCV prevalence in the general population are scarce and offer only data for slightly more than half of the 31 countries in the EU/EEA. Studies on pregnant women and prisoners are available for about half of the countries, and data on the prevalence of these infections among MSM are lacking for most EU/EEA countries.

The prevalence of HBV and HCV in the EU/EEA as a whole is estimated to be around 0.9 and 1.1 percent, respectively, with an estimated total of 4.7 million chronic HBV cases and 5.6 million HCV infected cases. These figures are likely to be an underestimation as a result of the inclusion of prevalence estimates among blood donors as a proxy for the general population in the absence of other evidence. However, when taking into account HBV and HCV data, the general population estimates obtained from the studies included in this review covered approximately 83% of the total European population, with the remaining 17% covered by blood donor estimates.

The lack of high-quality, recent, representative, nationwide prevalence estimates, and the overall heterogeneity of the available studies makes it challenging to gain an overview of the current epidemiological situation in the EU/EEA regarding chronic viral hepatitis. For a number of EU/EEA countries, robust HBV/HCV prevalence estimates are needed, both for the general population and specific risk groups. Increased efforts should be made to estimate the burden of hepatitis B and C, for example by developing a standardised seroprevalence survey. This would also provide robust strategic information for policymakers and help public health authorities to design appropriate secondary prevention interventions for HBV and HCV infection in the EU/EEA.

1 Background

Hepatitis B virus (HBV) and hepatitis C virus (HCV) can cause acute and chronic hepatitis and adversely affect the liver. People with chronic HBV and/or HCV infection remain infectious to others and are at risk of serious liver disease such as liver cirrhosis or hepatocellular carcinoma (HCC) later in life [1].

Transmission of HBV and HCV can occur via sexual, blood-blood contact or vertically (mother-to-child). There are several known high-risk groups for acquiring an HBV or HCV infection, these include people who require blood or blood products, people interned in prisons, people who inject drugs, people with multiple sexual partners, migrants originating from endemic regions, and new-borns from HBV or HCV chronically infected mothers (vertical transmission) [1].

The risk of developing chronic HBV infection depends on the age at infection: chronic infection results in 90% of infants infected at birth, in 30 to 50% of children infected between the age of one to four years, and in 1 to 10% of those infected at older age or as adults [2,3]. According to Schweitzer et al., an estimated 248 million people were chronically infected with hepatitis B worldwide in 2010 [4]. Approximately 780 000 persons die each year from HBV infection (650 000 from cirrhosis and liver cancer due to chronic hepatitis B infection and another 130 000 from acute hepatitis B) [5].

Initial infection with HCV is frequently asymptomatic or mild (70%–90% of cases). Of those infected, 50–80% later develop chronic infection, and those with chronic infection can eventually develop cirrhosis (up to 50%) and liver cancer (1–5%) over a period of 20 to 30 years [2]. The WHO estimates 30–150 million people globally have chronic hepatitis C infection, and 350 000 to 500 000 people are estimated to die each year from hepatitis C-related liver diseases [6].

Recently, the treatment options for HCV have greatly improved through the introduction of new drug therapies, and several new therapies are expected to be approved in the near future. As a result of advances in the treatment of chronic hepatitis B, a remission can be achieved in up to 90% of chronic hepatitis B cases [7,8]. The new direct acting antiviral therapy for HCV shows cure rates of over 90% [9].

There is a distinct geographical variation in both HBV and HCV prevalence and incidence in the EU/EEA. In parts of eastern and southern Europe, the prevalence of chronic infections is mostly high [10,11]. It has been estimated that across the EU/EFTA region almost 4.49 million people have a chronic hepatitis B virus infection [11]. In 2013, EU/EEA countries reported a total of 13 629 chronic HBV cases (7.4 cases per 100 000 population) to ECDC¹. Data indicate that the most common transmission route reported was mother-to-child transmission (43.5%). For chronic HBV cases, ECDC notes a steep rise in the number of infections and prevalence, which seems to be related to changes in reporting but may also reflect increases in local testing and screening practices among key populations [12].

Across the EU/EFTA region, an estimated 5.47 million are chronically infected with hepatitis C virus [11]. EU/EEA countries reported a total of 31 513 HCV cases to ECDC in 2013, 15.2% of which were classified as chronic (3.5 cases per 100 000 population)¹. The most common transmission route for chronic HCV was injecting drug use (77.6% of the data that included this information). For chronic HCV cases, no clear trend can be distinguished. It is likely that much of the variation in reported cases between countries reflects differences in testing and screening programmes among risk groups [13].

Rationale for the study

In 2011, ECDC started to coordinate EU-wide enhanced surveillance for hepatitis B and C based on annual data collection from EU/EEA Member States [12,13]. However, because chronic HBV and HCV infections are typically asymptomatic, notification data most likely do not reflect the real number of infections, but national screening and testing practices. It is generally felt that case-based surveillance data still do not have the robustness required to adequately inform primary or secondary prevention, resulting in the need for supplementary information in the form of prevalence data.

Information about the prevalence of HBV and HCV can help to better describe the current situation in the EU/EEA. In combination with the available surveillance data, European HBV and HCV prevalence data can also be used for benchmarking. In addition, in the wake of new treatment options, prevalence data are relevant for estimating the size of the chronically infected population and those in need of treatment. The improved options for antiviral treatment will also improve secondary prevention of both HBV and HCV. Prevalence data can help determine if

¹ Calculation based on reporting countries only.

there is a need to target and expand screening and testing for chronic HBV and HCV infection to those population subgroups with the highest prevalence.

The gold standard for assessing HBV and HCV prevalence in a population is to conduct a serosurvey on a randomised representative sample. In view of the costs and implementation challenges of such an exercise, a systematic review of existing hepatitis B and C prevalence studies is considered a robust tool to obtain up-to-date prevalence estimates for the EU/EEA.

In 2009, ECDC undertook a systematic review of the literature published between 2000–2009 to obtain insights into HBV and HCV prevalence in EU countries. The results of this review are presented in a technical report entitled *Hepatitis B and C in the EU neighbourhood: prevalence, burden of disease and screening policies* [10,14].

In 2015, ECDC conducted an update (2005–2015) of the previous systematic review, with the aim to provide estimates of the prevalence of HBV and HCV in the general population and in specific subgroups in the EU/EEA Member States, and to identify gaps in the available information.

2 Review methods

A systematic literature review was carried out to retrieve, assess and synthesise all available data on the prevalence of hepatitis B and C in the EU/EEA published between 2005 and 2015.

The study question was framed (see below) and a study protocol was developed. The search strategy built on the one used for the 2010 review [10]. After a full literature search, publications of interest were initially selected based on title and abstract. The full text of all publications selected during the title and abstract screening was then assessed for relevance. This was followed by extracting the relevant data from the selected publications and assessing the risk of bias for each study. All steps are described in detail below. The complete search strategy is described in Annex 5.

2.1 Research question

The objective of the review was captured in the following research question: What is the prevalence of HBsAg and anti-HCV in the EU/EEA countries in the general population and in the following subgroups:

- Blood donors
- Pregnant women
- People who inject drugs (PWID)
- Men who have sex with men (MSM)
- Prisoners
- Migrants

Thirty-one countries were included in the review: 28 EU Member States and three EEA countries (Norway, Iceland and Liechtenstein). HBV and HCV prevalence were defined as the presence of HBsAg and anti-HCV in serum, saliva or dry blood spot samples, respectively. The definitions of the various population subgroups are shown in Table 1.

Prevalence studies among itinerant ethnic groups, homeless people or other marginalised populations, sex workers, institutionalised patients in closed/fixed settings (for instance residential care homes for elderly people and orphanages) and returning travellers were not included in the review. The European outermost regions (Guadeloupe, French Guyana, Martinique and La Réunion, the Canary Islands, the Azores and Madeira) as well as the European overseas countries and territories (associated to Denmark, France, the Netherlands and the United Kingdom) were excluded. Review articles were not included in this review, as these typically do not present original data. However, the reference list of relevant reviews (where the disease, population, study period and setting matched the inclusion/exclusion criteria of this study) was checked for additional original articles not captured in the literature search.

Table 1. List and definition of key subgroups included in the systematic review

Population category	Definition
General population	People living in a defined geographical area (all ages or adults only), excluding specific low-risk populations such as children OR patients attending community and primary care settings, excluding hospitalised patients OR workforce or specific professional groups (e.g. workplace screening) excluding healthcare workers and specific recreational/sports-related population subgroups
Prisoners	Prison inmates and people incarcerated in custodial or prison settings including youth detention centres, excluding formerly incarcerated populations and people in other non-custodial closed/fixed institutions (such as secure psychiatric hospitals). Psychiatric prison hospital inmates (i.e. people with severe mental illness that are serving custodial sentences) are included.
MSM	Men who have sex with men
PWID	People who inject drugs, including current or past injectors, injectors of non-illicit drugs such as image or performance enhancing drugs. Excluded are non-injecting (illicit/street) drug users with drug use that can lead to blood-borne virus transmission (i.e. intra-nasal).
Pregnant women	Pregnant women undergoing antenatal care screening
Blood donors	First-time blood donors (pre-screened and non-pre-screened)
Migrants	Foreign-born migrants, not including Roma and other minorities, refugees, asylum seekers and their children

2.2 Literature search

Original research articles were retrieved from PubMed, Embase and Cochrane Library bibliographic databases in March 2015. The search strategies combined the concepts of HBV and HCV with 'prevalence'. Controlled vocabulary (i.e. MeSH and EmTree terms) and natural vocabulary (i.e. keywords) were used for representing the concepts in the search strategies. The search was limited to records published from 1 January 2005 to 12 March 2015, and no language restriction was applied. A geographical search string was used to limit the search to EU/EEA countries

and to studies with regional (i.e. European) and global scope. The geographic search strategy was developed by ECDC and underwent one testing round with the following results: negative predictive value (NPV) of 98.4% and a positive predictive value (PPV) of 66.4% in Embase and NPV of 97.6% and a PPV of 65.2% in PubMed. The geographical search strategy was not used for searching in the Cochrane Library. Search strategies are available in Annex 5.

The results of the search were transferred to an EndNote library. Duplicate records were automatically removed with EndNote tool. The Endnote library was then manually checked. The literature search was complemented by a manual search of references of relevant systematic reviews. In addition, ECDC's National Focal Points for HBV and HCV were consulted in May 2015 to review and validate the selected references on general population and high-risk group estimates for their country. They were also invited to provide additional published articles or grey literature. A total of 17 Member States responded by validating the list and/or providing additional references.

Articles in all EU/EEA languages were included because ECDC could provide translations.

To assess the prevalence of HBV and HCV among blood donors, PWID and migrants, additional sources of data were used. The Council of Europe and the European Monitoring Centre for Drugs and Drug Addiction (EMCDDA) are specialised institutions collecting data on blood donors and PWID, respectively. It was assumed that these data sources were reliable and that the data were comprehensive; therefore, no estimates from the literature were used to determine HBV and HCV prevalence in PWID and blood donors. Moreover, data on blood donors are often not reported in the literature, as was shown in the previous review [10]. Data on HBV and HCV prevalence among migrants in the EU/EEA were taken from a recent ECDC review on this topic [154] to avoid duplication.

The following three additional sources of data were used:

- For first-time blood donors: Council of Europe national blood donor data, 2014 report [15]
- For PWID: European Monitoring Centre for Drugs and Drug Addiction database on HBV and HCV prevalence in PWID [16] [17]
- For migrants: ECDC systematic review 'Epidemiological assessment of hepatitis B and C among migrants in the EU/EEA' [154]

2.3 Eligibility criteria and selection process

All records identified during the search were screened by title and abstract. Inclusion and exclusion criteria (Table 2) were developed in an iterative process involving all team members from both ECDC and RIVM. Two reviewers reviewed a random selection of five percent of the retrieved articles by title and abstract – in accordance with a predefined set of inclusion criteria – which resulted in an insufficient level of concordance (>10% disagreement). Inclusion criteria definitions were perfected and during a second round of parallel screening the two reviewers achieved a high level of concordance (>95%), after which the screening was continued separately. In cases of uncertainty about inclusion or exclusion, the reviewers consulted each other for a second opinion. Disagreements were resolved by consultation with a third team member.

Table 2. Inclusion and exclusion criteria

Inclusion criteria	Exclusion criteria
Articles published in 2005 or later reporting data from populations sampled in 2000 or later, including studies with data collection ending after 2000 (irrespective of start date)	Articles falling outside the specified sampling period or publication date range
Articles reporting data from one or more EU/EEA Member States and/or any of their regions/districts	Articles reporting data on non EU/EEA countries only
Articles reporting HBsAg/anti-HCV prevalence rates in humans	Articles not reporting data on HBsAg/anti-HCV prevalence or DNA/RNA or if virological markers tested for were not specified Article reporting only self-reported (i.e. unconfirmed) HBsAg/anti-HCV prevalence
Articles reporting data from the general population and/or key subgroups (Table 1)	Articles reporting data on specific high-risk groups only (Table 3)
	Articles reporting modelled data only Articles reporting only data from a study not conducted in humans, environmental studies, technology assessments (studies on diagnostic and/or laboratory methods) Opinion papers, editorials, guidelines or recommendations, perspectives, and correspondence articles, systematic reviews or meta-analyses Articles reporting data on the general population or pregnant women in countries with a population of >5 million inhabitants, but with a sample size <100 participants or with a sample size <50 participants for countries with a population of <5 million

After completion of the title and abstract screening, full-text publications were obtained using the libraries of RIVM, the Public Health Service Rotterdam-Rijnmond, and ECDC. Each reviewer individually screened the full texts of the selected references. Disagreement of selected full texts was resolved with mutual consent. If authors could not agree upon the issue, the reviewers consulted each other for a second opinion. Disagreements were resolved by consultation with a third team member. When a study was not considered relevant, the reason for exclusion was recorded in the data extraction file (Microsoft Excel). If more than one exclusion criteria was applicable, only one criterion was used to categorise the article.

Table 3. List and definition of high-risk groups excluded from the systematic review

Population category	Definition
Acute/chronic liver disease patients	Patients with acute or chronic liver disease
In-/outpatients	Patients in healthcare settings (as opposed to primary care), hospital care settings and emergency departments, including specific diagnosis-related populations such as <i>lichen planus</i> patients, lymphoma/leukaemia and all cancer patients, haemodialysis patients, and any other immunocompromised patients, including people living with HIV
Haemophiliacs	Haemophiliacs, recipients of blood products and organ transplant recipients
Healthcare workers	Healthcare services staff, including both healthcare professionals and support staff
Military	Military recruits
Children ²	Children aged 0–17 years

2.4 Data extraction

Data extraction was performed simultaneously with the full text screening. Relevant data were extracted from each included article and immediately recorded in the data extraction file (Microsoft Excel).

The unit for data extraction was not article, but study. A study was defined as a report of prevalence data on HBV or HCV for a defined population group, in a defined country, over a discrete period of time. According to this definition, a single article may include more than one study (e.g. comparing the same population over time; comparing different populations; reporting HBV and HCV prevalence). Studies published in more than one article were extracted only once, and the first publication was used as reference. Data from each study were extracted using a predefined set of variables covering: study characteristics, study population details, prevalence of HBV and HCV markers, including the type of sample collected and the laboratory test used. The complete list of variables is provided in Annex 6.

2.5 Assessment of quality and risk of bias

Each original article reporting the results of a prevalence study included in the analysis was evaluated for its quality based on a framework for making summary assessments of the risk of bias. The framework was developed ad hoc to assess the risk of selection bias, to determine the level of representativeness of the target population, and to judge the robustness of the estimates provided by the included studies. The framework was piloted, reassessed with the project team, and refined through a consensus-building approach. Four different frameworks were proposed to accommodate the differences between seroprevalence studies with regard to study design and sampling approaches toward different populations.

The risk of bias was not assessed for data on blood donors, PWID and migrants. Data for blood donors were obtained from the Council of Europe report, which collects annual data on national blood donations in Member States. For PWID no, or very limited, data were available to assess the risk of bias, and the study characteristics available are presented alongside the prevalence estimates.

In a review on HBV and HCV seroprevalence in migrants [154], the quality of individual studies was not assessed. This review, however, only contains those studies on migrants that were considered representative for the general migrant population. Criteria include sample size and study population. Studies on high-risk groups such as refugees, for example, were not included in the current review. The results of the assessment of the risk of bias for all included articles and populations is provided in Annex 4.

² Studies reporting seroprevalence of HBV or HCV in children only were excluded because they were not considered to be representative of the general population.

General population

The following four domains were considered as possible sources of selection bias in general population studies:

- Age
- Gender
- Sampling method and response rate
- Population coverage (i.e. the population covered by the sampling design in geographic/demographic terms)

Points were given for representativeness or a lower risk of bias in each domain (Table 4). A total score for risk of bias was calculated by adding up the scores in all four domains, resulting in a score of between 0 and 6. The highest score indicates the lowest risk of bias.

Table 4: Framework for assessing risk of bias: general population

Domain	Scores and description	
Age	0	1
	Clear age bias (towards children for example), not representative for general population; no information on age	No clear bias in age profile of respondents; representative for general population age distribution
Gender	0	1
	Clear bias in gender; no information to suggest representativeness for general population	No clear bias in gender distribution of subjects; could be considered representative if information is limited
Sampling method	0 – Non-random or non-exhaustive 1 – Exhaustive or random and <60% response rate or no info 2 – Exhaustive or random and >60% response rate	
Population coverage	0 – Single centre/local; 1 – Multi-centre/local or regional; 2 – Multi-centre/national	

Pregnant women

The following two domains were considered as potential sources of selection bias in studies on pregnant women:

- Sampling method; response rate not included due to lack of denominator data
- Population coverage (i.e. the population covered by the sampling design in geographic/demographic terms).

Points were given for representativeness or a lower risk of bias in each domain (Table 5). A score for the combined risk of bias was calculated (0 to 3), with a score of 3 indicating the lowest risk of bias.

Table 5: Framework for assessing risk of bias: pregnant women

Domain	Scores and description	
Sampling method	0	1
	Non-random or non-exhaustive	Exhaustive or random
Population coverage	0 – Single centre/local; 1 – Multi-centre/local or regional; 2 – Multi-centre/national	

MSM

Only the domain 'sampling venue coverage' was included in the framework for assessing the risk of bias in studies on MSM (Table 6). Studies that took samples from multiple venue types were rated as having a lower risk of bias than studies that only explored single venues or multiple venues of the same type. Studies were assigned zero to 2 points, with a score of 2 indicating the lowest risk of bias.

Table 6: Framework for assessing risk of bias: MSM

Domain	Scores and description	
Sampling venue coverage	0 – Single venue; 1 – Multi-centre/single venue type; 2 – Multi-centre/multi-venue type	

Prisoners

The following five domains were considered as potential sources of selection bias for studies in prisoners:

- Age
- Gender
- Proportion of PWID (or used as a selection criterion)
- Sampling method
- Population coverage (i.e. the population covered by the sampling design in geographic/demographic terms)

Points were given for representativeness or a lower risk of bias in each domain (Table 7). A score for the combined risk of bias was calculated (0 and 6), with a score of 6 indicating the lowest risk of bias.

Table 7: Framework for assessing risk of bias: prisoners

Domain	Scores and description	
Age	0	1
	Clear age bias (i.e. among juvenile offenders only); no information	No clear bias in age profile of subjects
Gender	0	1
	Clear bias in gender; no information	No clear bias in gender distribution of subjects; could be considered representative if information is limited
% PWID	0	1
	Exclusively among PWID/former PWID prisoners	PWID not used to select subjects; no bias toward PWID
Sampling method	0	1
	Non-random or non-exhaustive	Exhaustive or random
Population coverage	0 – Single centre/local; 1 – Multi-centre/local or regional; 2 – Multi-centre/national	

2.6 Data analyses

General approach

All available estimates were rounded to one decimal point. Weighted or standardised prevalence estimates, if available, were preferred over unweighted or crude estimates. Confidence intervals (CI) of 95% were calculated using the Fisher exact method, unless already reported.

Based on the score from the assessment of the bias risk in the four population groups, an algorithm for data inclusion in the analysis was developed. Studies with higher quality (see criteria below) were included in the comparative analysis. HBV and HCV prevalence estimates from all eligible studies (i.e. all data points) are presented in the overview tables (Annex 2) and the country profiles (Annex 3).

General population

General population estimates were reported separately for adults and children where possible, and estimates for adults were included in the analysis. Studies in the general population with a score for risk of bias greater or equal to 4 (higher quality) were pooled. When there was a difference greater than 1% between higher quality estimates, regional estimates were reported separately.

HBV and HCV prevalence maps of Europe were produced for the general population, representing data from higher quality studies. Countries for which no studies with a score of 4 or more were available were shaded grey or labelled 'no data'. Maps were produced with EMMA, the ECDC Mapping and Multi-Layer Analysis tool. Countries in the prevalence map were categorised based on the following ranges: <0.5%, 0.5–1%, 1–2%, 2–8%.

All higher quality estimates (risk of bias score ≥4) retrieved for each country for the general population were presented in a forest plot. Separate forest plots were prepared for HBV and HCV infections using Microsoft Excel. The parameters displayed in each forest plot are country, sampling period, prevalence estimate, and 95% CI.

Pregnant women

HBV and HCV prevalence estimates obtained from studies in pregnant women with a risk of bias score greater or equal to 2 were considered of higher quality and pooled (when possible). Higher quality estimates were presented in separate forest plots for HBV and HCV infections. The parameters displayed in each forest plot are country, sampling period, prevalence estimate, and 95% CI.

First-time blood donors

A summary table with HBV and HCV estimates for first-time blood donors was created by using data from the latest Council of Europe report (2011 data) [15]. For countries with no data reported in the latest report, data from the most recent previous Council of Europe report were used. For the following countries, older data were used: Austria (2010), Poland (2010), Slovenia (2009), Sweden (2009), Cyprus (2008), Portugal (2006), Latvia (2003). The number of first-time blood donors, the number of HBV cases, and the number of HCV cases were retrieved and shown in a table.

European HBV/HCV prevalence estimates

In order to estimate the current burden of chronic hepatitis B and C in the EU/EEA, an algorithm based on study quality was used to estimate the prevalence of HBV and HCV in the general population of each EU/EEA country. General population crude estimates and blood donor data identified in this review were combined using the following algorithm: if a pooled higher quality general population crude prevalence estimate was available for a

country, it was used to determine the HBV and HCV prevalence in that country. If there was no higher quality estimate available, general population estimates with a lower quality were pooled (when possible) and used as an estimate of a country's HBV and HCV prevalence. If no general population prevalence estimates were available, data on the prevalence of HBV and HCV in blood donors were used as a prevalence measure for the country. To determine the total number of HBV and HCV cases in each country, Eurostat 2014 data were used; the total population size was multiplied by the estimated prevalence in each country.

MSM

No prevalence estimates were pooled because the number of eligible studies among MSM was small and had a higher risk of bias. All retrieved estimates, irrespective of the risk of bias score, are presented in a forest plot. Separate forest plots were prepared for HBV and HCV prevalence using Microsoft Excel. The parameters shown in the forest plots are country, sampling period, prevalence estimate and 95% CI.

Prisoners

HBV and HCV prevalence estimates obtained from studies with a risk of bias score greater or equal to 3 and in adult populations were considered of higher quality and pooled when possible. All higher quality estimates for prisoners are presented in a forest plot. Separate forest plots were prepared for HBV and HCV infections using Microsoft Excel. The parameters displayed in each forest plot are country, sampling period, prevalence estimate, and 95% CI. Estimates for adult and juvenile populations are shown separately.

PWID

A summary table with HBV and HCV prevalence estimates among PWID was created using EMCDDA data. The most recent available data were downloaded from the EMCDDA website [16,17]. National and subnational prevalence estimates were retrieved. The summary table includes sampling period, sample size, national prevalence estimates, and 95% CI.

Migrants

Migrant data from the ECDC systematic review 'Epidemiological assessment of hepatitis B and C among migrants in the EU/EEA' were used [154]. Only HBC and HCV prevalence estimates for foreign-born first generation migrants obtained from studies with a sample size of >100 were included. When multiple estimates (by country of origin) were available from a Member State, results were pooled. A summary table of all estimates (alphabetically by Member State) was prepared. The table includes country of origin, sampling period, sample size, prevalence and CI.

Country profiles

All country-specific HBV and HCV prevalence estimates retrieved from eligible studies are presented in country profiles which include:

- Summary tables with details of all included studies and an assessment of the related risk of bias for HBV and HCV
- Forest plots summarising HBV and HCV prevalence estimates from all eligible studies for all relevant population groups, including blood donors and migrants.

HBV and HCV prevalence estimates for PWID were reported separately due to heterogeneity of the data, for example in some cases only a prevalence range was available. The country profiles are shown in Annex 3.

3 Review results

3.1 Systematic literature search

The literature search identified 9 379 articles, 142 of which were selected – based on title and abstract – for the ‘general population’ category. The title and abstract screening yielded 50 articles for the category ‘pregnant women’, 17 for ‘MSM’, and 57 for ‘prisoners’. A manual search and Member State consultation yielded additional articles for the categories ‘general population’ (9), ‘prisoners’ (7), ‘pregnant women’ (5), and ‘MSM’ (3).

Of the 284 full-text articles retrieved (three publications were unavailable), 148 were on the general population, 61 on prisoners (three articles unavailable), 55 on pregnant women, and 20 on MSM. After the full-text screening, the number of eligible articles was further reduced: 48 articles on the general population were considered eligible; 32 on pregnant women; 32 on prisoners; and 13 on MSM.

Some publications reported both HBV and HCV prevalence, and one publication reported results from multiple countries. PRISMA³ flowcharts with the results of the literature search are presented in Annex 1.

The number of prevalence estimates per country for HBV and HCV are presented in Table 8 per population group. Estimates derived from EMCDDA data (HBV and HCV in PWID), the Council of Europe report (HBV and HCV in first-time blood donors) and the ECDC epidemiological assessment of hepatitis B and C among migrants in the EU/EEA (HBV and HCV in migrants) are not included in this table.

For a total of 15 countries, no recent estimates for HBV and HCV prevalence in the general population were available. For the following subpopulations, HBV/HCV prevalence estimates were not available for a number of countries: pregnant women (HBV: 20 countries, HCV: 23 countries), MSM (HBV: 27, HCV: 24), and prisoners (HBV/HCV: 12).

3.2 Prevalence of chronic HBV and HCV infections

General population

Fifty estimates for the prevalence of HBV in the general population were obtained from eligible studies; for HCV, 45 estimates were retrieved. A summary of these estimates with additional information on study characteristics and population is given in Tables A5 and A6 (Annex 2). The articles used for estimating the prevalence per country in Figures 1a and 1b are marked with asterisks in Tables A5 and A6. The forest plots in Figures 2 and 3 show all higher quality, pooled or standardised estimates for the general population for HBV and HCV.

Of the 50 prevalence estimates for HBV, representative estimates for the general population (risk of bias score ≥ 4) were available for 13 countries: Belgium, Croatia, the Czech Republic, France, Germany, Greece, Hungary, Ireland, Italy, the Netherlands, Romania, Slovakia and Spain (Figure 1a). The number of estimates available per country ranged from one estimate for Hungary and the United Kingdom to 10 estimates for Italy. For HBV, the prevalence in the general population ranged from 0.1% in Ireland to 4.4% in Romania (Figure 2). Greece and Romania account for the highest HBV prevalence, 3.3% and 4.4% respectively, while the vast majority of countries have an HBV prevalence around or below 1%. The most recent estimate for Greece is much higher than the prevalence range of 0.0%–2.1% reported in the previous review [10]. However, the most recent estimate is completely based on population data from Crete only because no nation-wide estimate for Greek was available for this review. Several higher quality prevalence estimates were available for Italy which, when pooled, resulted in an HBV prevalence of 0.7%. However, single study prevalence estimates ranged from 0.5% in the region of Apulia, southern Italy, to 5.8% in the province of Bergamo, northern Italy, thus showing a high heterogeneity in the available estimates of HBV prevalence (Annex 2 Table A5 and Annex 3).

HCV prevalence estimates that were considered representative for the general population (risk of bias score ≥ 4) were available for 13 countries: Belgium, Croatia, France, Germany, Greece, Hungary, Ireland, Italy, the Netherlands, Latvia, Romania, Slovakia and Spain (Figure 1b). The number of estimates available varied between one estimate (Belgium, Greece, Hungary, Ireland, Latvia, Romania and Slovakia) and 14 estimates for Italy. The HCV prevalence in the general population reported ranged from 0.1% in Belgium, Ireland and the Netherlands to 5.9% in Italy (Figure 3). Countries with a relatively high HCV prevalence were Romania (3.2%), Greece (2.2%), Latvia (2.4%) and Slovakia (2.0%). For Greece, the present estimate is based on population data from Crete. Italy and Spain had the largest number of prevalence estimates available. Spain had one higher quality estimate, which reported an HCV prevalence of 1.1%, as shown in Figure 2. The other estimates show a range from 0.4% in Barcelona to 0.6% in the working population of Murcia and Madrid to 1.5% in multiple GP offices around Barcelona (Annex 2, Table A6; Annex 3). The highest prevalence estimate for Spain (1.5%) shows a very large confidence interval (Annex 3).

 Pooled estimates were used for Germany and Italy

Pregnant women

Twenty-seven estimates on HBV prevalence in pregnant women were retrieved from eligible studies; for the same group, 15 estimates on HCV prevalence could be found. A summary of these estimates with information on study characteristics and population is presented in Tables A7 and A8 (Annex 2). The forest plots in Figures 4 and 5 show all higher quality, standardised or pooled estimates with regard to pregnant women in the EU/EEA.

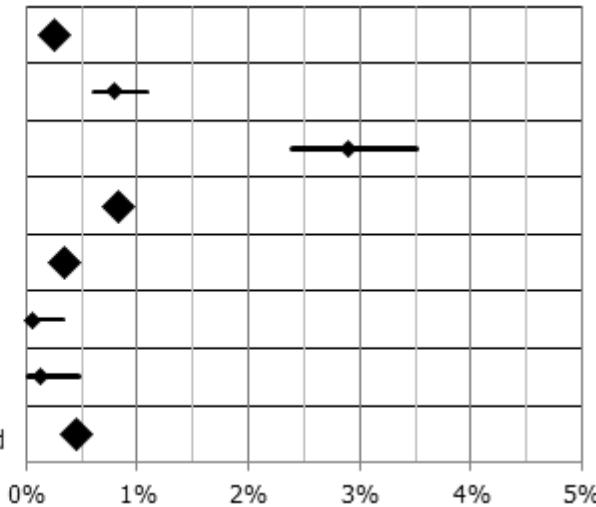

Higher quality estimates (risk of bias score ≥ 2) for HBV prevalence were available for seven countries, ranging from 0.1% in Norway and Spain to 0.8% in France and Italy (Figure 4). Pooled estimates were available for four countries. For nine countries, more than one estimate was available, with Greece having the highest number of estimates. For the Netherlands, three consecutive estimates for HBV in pregnant women were available (2006–

2008). HBV prevalence in these years changed from 0.3% in 2006 and 2007 to 0.4% in 2008 (Annex 2, Table A7; Annex 3).

Of the 15 estimates identified for HCV prevalence among pregnant women, higher quality estimates (risk of bias score ≥ 2) were available for four countries: Slovenia, Spain, Italy and Norway, with prevalence ranging from 0.1% in Slovenia to 0.9% in Norway (Figure 5). For Slovenia, several estimates were available (2003, 2009 and 2013), which could be pooled (Figure 5). HCV prevalence among pregnant women in Slovenia in 2003 was 0.2%, while 2009 and 2013 estimates show HCV prevalence at 0.1% (Annex 2, Table A8; and Annex 3).

First-time blood donors

The prevalence of HBsAg and anti-HCV in first-time blood donors by country was available for 30 countries and is presented in Table 9. A comprehensive table of the data is shown in Table A9 in Annex 2. For Latvia and Portugal, no details were available on the absolute number of positive HBV or HCV cases and first-time blood donors, and no 95% Confidence Intervals (95% CI) could be calculated.

The prevalence of HBV among first-time blood donors ranged from 0.0% in Finland and Luxembourg to 3.2% in Bulgaria. Most countries (60%) had an HBV prevalence that was below or around 0.1%.

The prevalence of HCV among first-time blood donors ranged from 0.0% in Iceland to 2.2% in Latvia, although the latter is the least recent estimate (2003), and is presented in Table 9. Most countries had an HCV prevalence below or around 0.1%.

Table 9. Prevalence of HBsAg and anti-HCV in first-time blood donors, EU/EEA, source: Council of Europe, 2011*

Country	Prevalence of HBsAg (95% CI) ^a	Prevalence of anti-HCV (95% CI) ^a	Council of Europe Report

* Adapted from Tables 1 and 7.1, Council of Europe Report 2011 [15]

^a Calculated using the Fisher exact method for 95% CI when data on number of cases were available

^b France: The French blood service is composed of the French National Blood Service (EFS) (17 blood centres) and the French Army Transfusion Service (CTSA) with one blood centre. Data of both organisations are reported.

^c Latvia: After 2002, only data on HIV were presented; no HBV/HCV data were available

European HBV/HCV prevalence estimates

An overview of the estimates and data used for each country can be found in Table A10 in Annex 2. Based on general population and blood donor estimates to determine the current burden of chronic HBV, the HBV prevalence in the EU/EEA as a whole is estimated to be 0.9% (95% CI 0.7–1.2), corresponding to almost 4.7 million HBV HBsAg-positive cases. The United Kingdom has the highest estimated number of HBV cases (1 093 240). This assessment, however, is based on a lower quality prevalence estimate (Table A10, Annex 2). Romania also has a high estimated number of HBV cases (877 682), and Spain, France and Italy all have around 400 000 to 500 000 HBV cases. For both Finland and Luxembourg, zero HBV cases were computed because only blood donor prevalence estimates were available.

For HCV, the estimated EU/EEA prevalence is 1.1% (95% CI 0.9–1.4), corresponding to around 5.6 million anti-HCV-positive cases. Italy has the highest estimated number of HCV cases (2 510 324), with the next highest number of cases being 771 762 for Poland (based on a lower quality estimate). France, Romania, Spain and the United Kingdom all have around 350 000 to 450 000 estimated HCV cases. For Iceland, no HCV cases were calculated; only prevalence estimates based on blood donor data were available.

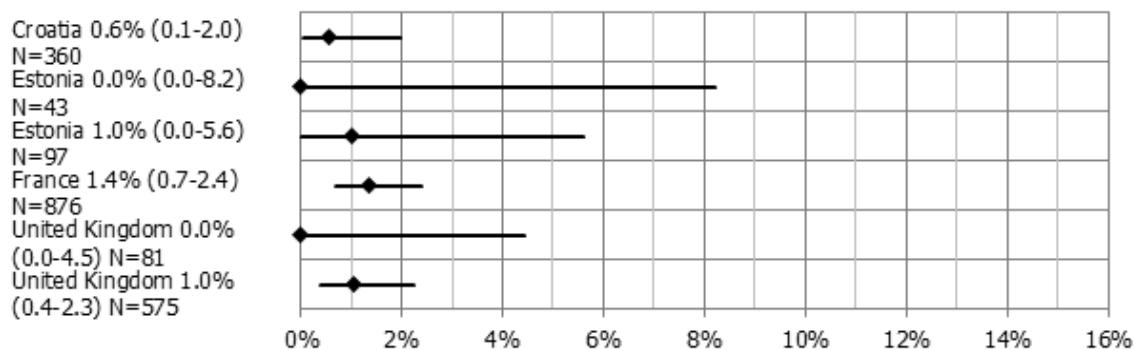

MSM

For the prevalence of HBV/HCV in MSM, 6 (HBV) and 11 (HCV) estimates were obtained from eligible studies. All estimates are included in the forest plots (Figures 6 and 7) to compensate for the low number of studies and the overall lack of good-quality studies, which are all based on convenience sampling. A summary of these estimates with information on study characteristics and population is given in Tables A11 and A12 (Annex 2).

For HBV, the prevalence in MSM ranged from 0.0% in Estonia and the United Kingdom to 1.4% in France. Multiple estimates were only available for Estonia and the United Kingdom; however, the single estimates for Croatia and France were of higher quality (Figure 6). The Estonian estimates were from different sampling periods; in 2013, the reported HBV prevalence was 0.0% and in 2014–2015, reported prevalence was at 0.1%. Both estimates, however, do have a large confidence interval, ranging from 0.0% to 8.2% for the 2013 estimate and from 0.0% to 5.6% for the 2014–2015 estimate.

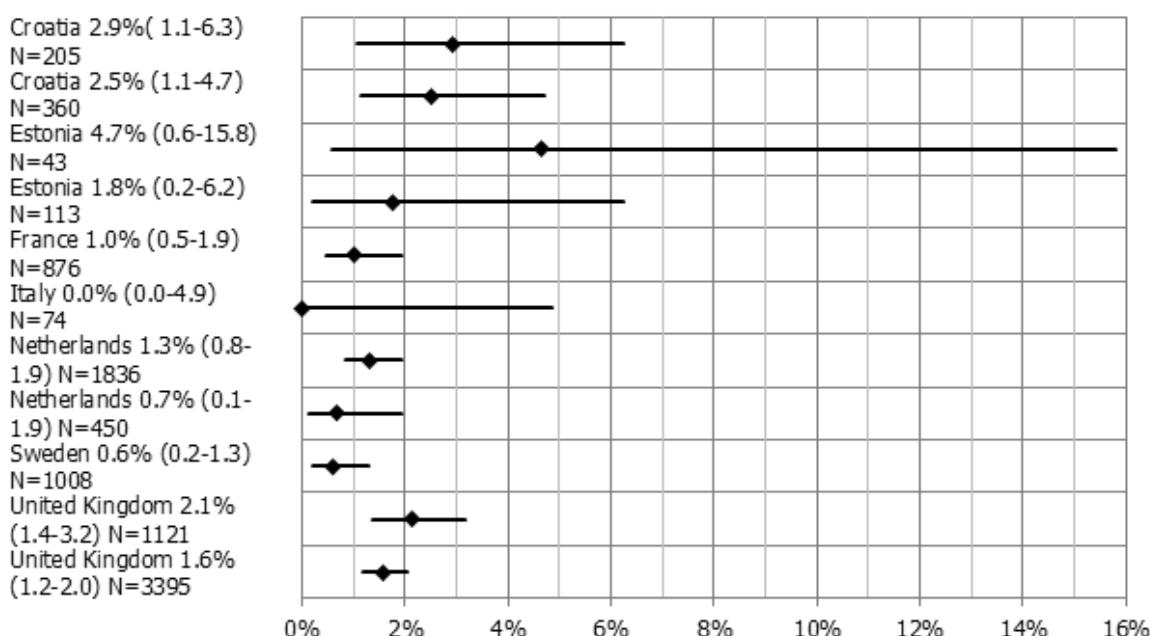

The prevalence of HCV among MSM ranged from 0.0% in Italy to 4.7% in Estonia. For Croatia, Estonia, the Netherlands and the United Kingdom multiple estimates were available (Figure 7). Most countries show an HCV prevalence below or around 2%, with the exception of Estonia and Croatia (2.9%). Estonia has two divergent estimates for HCV prevalence in MSM: one from 2013, reporting a 4.7% prevalence, and one from 2014–2015, reporting a 1.8% prevalence. The highest estimate (4.7%) also shows a very large confidence interval, ranging from 0.6% to 15.8%.

Prisoners

Eligible studies yielded 15 estimates for HBV prevalence in prisoners and 43 estimates for HCV prevalence in the same population group. HBV and HCV prevalence estimates for 11 countries based on higher quality studies (risk of bias score ≥ 3) are presented in Figures 8 and 9. A summary of all estimates with information on the study characteristics and population is given in Tables A13 and A14 (Annex 2).

HBV prevalence estimates that were considered representative for prisoners were available for 11 countries: Bulgaria, Croatia, Finland, France, Hungary, Ireland, Italy, Luxembourg, Portugal, Spain and the United Kingdom. The only countries with multiple estimates were Croatia (3) and the United Kingdom (2), as shown in Annex 2: Table A14. For HBV, the prevalence in prisoners ranged from 0.3% in Ireland to 25.2% in Bulgaria (Figure 8). Countries with high HBV prevalence were Portugal (10.8%), Luxembourg (7.0%) and Italy (6.7%). For Croatia, estimates obtained over different sampling periods were available, consistently reporting an HBV prevalence of 1.3% in prisoners (Annex 2: Table A13, Annex 3).

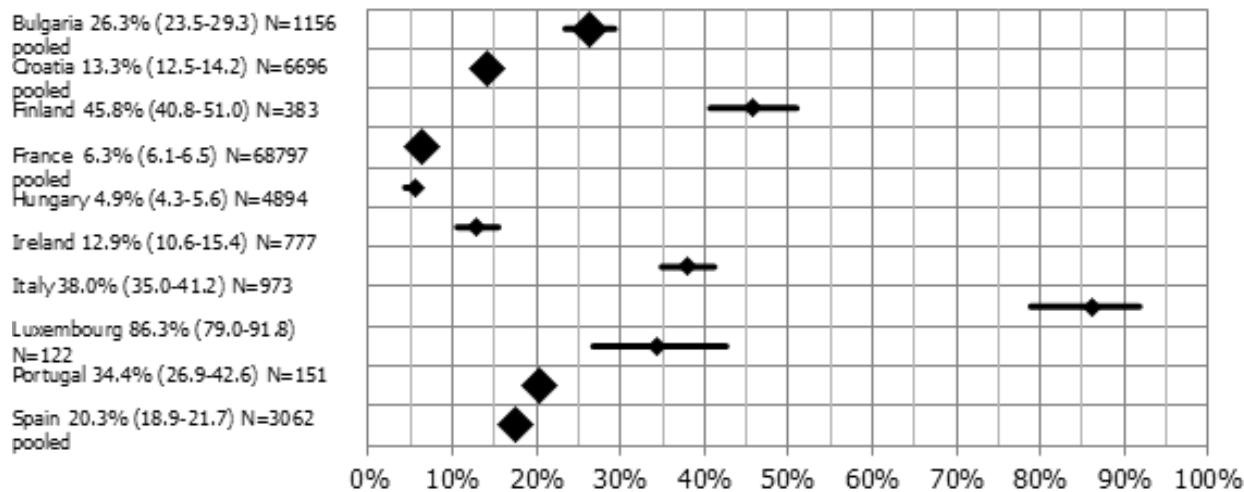

HCV estimates that were considered representative were available for 11 countries, ranging from 4.9% in Hungary to 86.3% in Luxembourg (Figure 9). Pooled estimates were available for five countries. Overall, multiple estimates were available for eight countries, with Spain having the highest number of estimates (13). For Spain, consecutive estimates were available for HCV in prisoners (2000–2009). The HCV prevalence in these years changed from 44.9% in 2000 to 25.3% in 2009, showing a decrease in prevalence over time and, combined with other estimates, resulted in a pooled estimate of 20.3% (Annex 2: Table A14, Annex 3).

PWID

The prevalence of HBsAg and anti-HCV in PWID is presented in Table 10 by country. Comprehensive tables of the PWID data including regional estimates are shown in Tables A15 and A16 in Annex 2.

National estimates on HBV were available for seven countries: Croatia, Cyprus, Greece, Hungary, Ireland, Latvia and Portugal. The national prevalence estimates of HBV ranged from 0.5% in Croatia, Hungary and Ireland to 6.3% in Portugal.

National estimates for HCV were available for 16 countries: Austria, Croatia, Cyprus, the Czech Republic, Denmark, Finland, Greece, Hungary, Ireland, Italy, Latvia, Malta, Norway, Portugal, Slovenia and the United Kingdom. National prevalence estimates of HCV in PWID ranged from 13.8% in Malta to 84.3% in Portugal.

^a Samples with sample size under N = 10 were excluded.

^b Calculated using the Fisher exact method for 95% CI.

^c Greece: Two national estimates were pooled.

^d Italy: Data collection system was changed. Up to 2011, aggregated data were collected. Detailed data became available in 2012. Data from 2012 and later are therefore not comparable with previous years.

^e Latvia: Status for 'IDUs' changed from unknown to 'ever IDUs' after 2011.

^f United Kingdom: Data collection for Scotland is not by calendar but by tax year (i.e. from April 2015 to March 2016).

Migrants

The prevalence of HBsAg and anti-HCV in the representative general migrant population is presented in Table 11. Comprehensive tables of the HBV and HCV migrant data are shown in Tables A17 and A18 in Annex 2. Estimates were available for five countries: Greece, Italy, the Netherlands, Norway and the United Kingdom. Studies from the Netherlands and the United Kingdom reported HBV prevalence estimates among several migrant groups by country of origin. According to the available estimates, the prevalence of HBV ranged from 0.0% to 17.4% in migrants. The highest prevalence is reported among migrants from countries in south-east Asia, irrespective of their current country of residence [ECDC report, in press].

For three countries, Italy, the Netherlands and the United Kingdom, HCV estimates were available. Studies from the Netherlands and the United Kingdom reported HCV prevalence estimates for a variety of migrant groups by country of origin. The anti-HCV prevalence in migrants ranged from 0.0% to 7.1%, with the highest prevalence reported among migrants from Eastern Europe in Italy [ECDC report, in press].

4 Discussion

This systematic literature review aims to collect, assess and collate the available evidence on the prevalence of HBV and HCV in the general population and six population subgroups in EU/EEA countries, and to identify gaps in the currently available evidence.

There was widespread heterogeneity in the identified studies, which limited comparability. In order to identify representative estimates for the general population and other target populations in each EU/EEA country, the risk of bias was assessed for each study. Preference was given to the higher quality studies; however, corresponding higher quality estimates were not available for many countries. Limited geographical coverage in studies was also a frequent issue; regional or local estimates were more regularly available than national estimates.

General population, pregnant women, and first-time blood donors

Based on the data extracted from the literature reviewed in this study, the prevalence of HBV and HCV infections in the general population varied widely between EU/EEA countries. Countries in the eastern and southern part of the EU/EEA generally had a higher HBV and HCV prevalence than countries in the northern and western parts.

HBV prevalence ranged from 0.1% in Ireland to 4.4% in Romania. Comparing these percentages with the estimates presented in the previous report [10], no clear pattern is discernible. For nine countries, HBV prevalence estimates were available in both reports. Although no statistical analysis of differences was performed, it was observed that HBV prevalence in Belgium and Ireland remained the same, while HBV prevalence has increased in Greece, Italy, Slovakia and the Netherlands. A decrease in HBV prevalence was found in Germany, Romania and Spain. A possible explanation for the increase in prevalence estimates in Greece is the limited geographical coverage of the studies included in this review: the current HBV prevalence estimate of 3.3% for Greece, which is higher than the one in the previous review (0.0%–2.1%), refers to the population of Crete only. No national estimate for Greece was available for the publication period in this review. Schweitzer et al. [4] estimated that Greece has a national HBsAg prevalence of 0.97%. Heterogeneity between studies was high between Italian studies; single-study prevalence estimates showed a wide range in HBV prevalence (0.5%–5.8%). However, the available higher quality studies from Italy reported consistent prevalence estimates. In the Netherlands, the increase in chronic HBV prevalence (from 0.1% in 1996 to 0.2% in 2007) is reportedly related to demographic changes over time resulting in an increase in the proportion of the population born in HBV-endemic countries [18].

The anti-HCV prevalence in this report ranges from 0.1% in Belgium, Ireland and the Netherlands to 5.9% in Italy. A comparison of HCV prevalence for the nine countries with higher quality HCV estimates in both reports suggests that prevalence is decreasing in half of the countries. Notable exceptions are Greece, where an increase is observed, and Belgium and Germany, where the prevalence stays the same. For Greece, however, the restricted geographical coverage (Crete) of the current estimate limits the generalisability of this finding. For Italy, the geographical coverage of the HCV estimates also influences the current findings. In the previous report [10], Italy had a geographical gradient for HCV, with higher prevalence in the southern regions, as compared to central and northern Italy. Similarly, the studies included in this review showed a high heterogeneity, although no clear north-to-south gradient was found. However, some estimates for HCV in Italy had a local geographical coverage and the investigated communities were in a region that was considered hyperendemic for HCV [19], which might have skewed the overall prevalence estimate. It is noteworthy that in this study, HCV prevalence among people older than 50 years (27.6%) was considerably higher than in younger people (3.0%) [19].

In pregnant women, the HBV and HCV prevalence estimates were higher when compared to the general population in nearly all countries. This is consistent with the results of the 2009 report [10]. A possible explanation may be found in the contribution of migrants, who are often underrepresented in general population studies but overrepresented among pregnant women. Italy and Spain are the exceptions, where the HBV and HCV prevalence estimate for pregnant women showed a lower prevalence than the estimate for the general population. This likely reflects the impact of the early start of universal HBV vaccination programmes in these countries [20] as well as the lower seroprevalence levels observed in young adults as compared to older age groups [19].

HBV and HCV prevalence in first-time blood donors can generally be regarded as the lower limit of the prevalence estimate in the general population; however, pre-selection of blood donors, where implemented, makes them an unrepresentative sample of the general population. The data in this review also show that the HBV and HCV prevalence in first-time blood donors is lower than in the general population for all countries, although some confidence intervals overlap. Nonetheless, using blood donor or pregnant women data as a proxy for HBV and HCV prevalence estimates for the general population is not optimal.

The prevalence of HBV and HCV in the EU/EEA as a whole is estimated to be around 0.9 and 1.1 percent, respectively, with an estimated total of 4.7 million chronic HBV cases and 5.6 million HCV infected cases. These

figures are likely to be an underestimation as a result of inclusion of prevalence estimates among blood donors as proxy for the general population in the absence of other evidence. However, when taking into account both HBV and HCV data, general population estimates, obtained from included studies, accounted for approximately 83% of the total European population, with the remaining 17% covered by blood donor estimates.

High-risk populations

The heterogeneity and lack of comparability between identified studies was particularly noticeable for high-risk populations.

For MSM, very few prevalence estimates were available. This lack of studies in many countries raises the question whether MSM are considered to be a key group in these countries. When comparing HBV prevalence among MSM to that of the general population in countries where both estimates were available, HBV prevalence was higher in France, and lower in Estonia and the United Kingdom. For HCV, all countries showed a higher prevalence among MSM except for France, where HCV prevalence in the general population was higher. Estonia was one of the countries with more than one prevalence estimate available for both infections, but the studies had very small sample sizes and do not necessarily report a prevalence representative of the situation in the MSM community in the country. A higher HCV prevalence among MSM is often seen in HIV-positive men [21], but studies conducted among HIV-positive people were not included in this review (Table 3).

In all countries, the prevalence estimates of HBV and HCV were higher among PWID than in the general population, and in all countries, PWID had the highest HCV prevalence. This can be expected, as intravenous drug use is one of the most important risk factors for HCV infection. The prevalence of anti-HCV among PWID was considerably higher than that of HBsAg in all countries that provided data on both types of infections among PWID. This may be explained by the relatively low risk of developing chronic HBV infection when the infection is acquired as an adolescent or adult through injecting drug use [3].

The HBV and HCV estimates among prisoners were higher than in the general population in all countries. For HCV, and to a lesser extent for HBV, this is related to overrepresentation of PWID among prisoners. Longitudinal data from Spain showed that the anti-HCV prevalence in prisoners declined from 45% in 2000 to 25% in 2009. Similar to what was observed among PWID, in countries that supplied data for both types of infections, the prevalence of HCV among prisoners was higher than that of HBV. Nevertheless, prisoners showed the highest HBV prevalence for all countries. A possible explanation for the relatively high prevalence of chronic HBV in prisoners is the overrepresentation of foreign-born people in the prison population [22].

The number of HBV and/or HCV prevalence studies in migrants is limited. Available data from the ECDC systematic review 'Epidemiological assessment of hepatitis B and C among migrants in the EU/EEA' [154] shows that in nearly all countries and ethnic groups the estimated prevalence of both HBV and HCV is higher among migrants compared with the general population. The only exception is Italy, where the estimated general population HCV prevalence is higher than the prevalence found in migrants groups, with the caveats discussed above.

Gaps in evidence at EU/EEA level

In the 2009 systematic review, estimates for the general population were identified for 13 countries, for both HBV and HCV prevalence [10]. For this review, estimates were identified for a total of 15 countries with available HBV prevalence estimates in the general population and for a total of 16 countries with available HCV estimates. For some countries that were included in the previous report no general population prevalence studies were available for inclusion in this review, namely Cyprus, the Czech Republic, Denmark, Finland and Sweden for HBV prevalence, and Bulgaria, the Czech Republic and Sweden for HCV prevalence. This is mainly due to the selected time frame (articles published between 2005 and 2015) and shows the lack of recent prevalence data for some countries.

Other than perhaps the population size of the country, no clear geographical distribution across the EU can be observed in the availability of (higher quality) estimates in any of the targeted population groups. For one country, Liechtenstein, no information about HBV and HCV prevalence was available for any of the population groups. For Cyprus, Iceland and Malta, only prevalence data on first-time blood donors were available and for five countries, only lower quality estimates were available: Austria, Estonia, Lithuania, Poland and Sweden. However, Estonia and Sweden were two of the few countries that reported HBV and HCV prevalence in MSM.

When comparing countries that have at least one higher quality estimate for HBV in the general population with countries for which no estimates are available, the countries with higher quality estimates appear to have a slightly lower prevalence (and more studies with random sampling). There are more studies on countries with higher quality estimates for HCV in the general population than for HBV. Some of the countries for which no higher quality estimates are available have well-designed studies but these studies often only cover a geographically limited region, making it difficult to extrapolate the reported prevalence. In general, research interests, existing resources

and public health priority agendas may contribute to the availability of recent and higher quality HBV and HCV estimates at the national or subnational levels.

Other gaps in the available evidence are the lack of recent data on blood donors (for seven countries no data were available in the 2011 Council of Europe report) and the large number of countries without data on the prevalence of HBV and HCV infections among PWID. In addition, the general lack of good prevalence data for MSM is problematic. The included MSM studies usually had small sample sizes, resulting in reported estimates with large confidence intervals. A few more estimates were available for HCV prevalence in MSM compared to HBV, but data were still far from comprehensive. Generally, the overall lack of available estimates, lack of comparability and poor geographical representativeness of studies show that there is still a need for further research.

Strengths and limitations

This literature review builds on and expands previous work conducted by ECDC to provide an overview of the current situation with respect to HBV and HCV prevalence in the EU/EEA, both in the general population and among high-risk groups. It was limited to studies published after 2004 to better reflect recent developments but this restriction potentially excludes relevant data. The risk of bias was assessed for each study by using a pre-defined methodology to mitigate the impact of differences in study design and conduct (e.g. study population selection and sampling, different laboratory tests, and sample types), but comparisons of the prevalence estimates across countries should still be made with caution.

Instead of focussing on trends over time and differences between genders, this review compared absolute differences between the current and previous estimates [10]. According to Schweitzer et al., western European countries showed a consistently low HBV prevalence over time, while in a few countries in eastern Europe a tendency towards an increasing HBV prevalence became noticeable [4].

This report explores anti-HCV prevalence, as opposed to HCV RNA, the marker of HCV chronic infection. Although the information on HBV DNA and HCV RNA prevalence was also extracted, nucleic acid amplification confirmatory testing was performed or reported in too few studies to warrant an analysis of this indicator: information about DNA or RNA confirmation was available for only 8% of HBV studies and 33% of HCV studies on the general population.

A round of data validation with Member States provided additional information and further supplemented the evidence base. Despite that, the use of a geographical string and single reviewer screener may still have resulted in incomplete identification of the evidence base.

For PWID, first-time blood donors and migrants, other data sources were used rather than studies identified in this systematic review. For migrants, prevalence data were derived from 'Epidemiological assessment of hepatitis B and C among migrants in the EU/EEA' [154]. For blood donors, recent national prevalence estimates were available for most countries.

Estimates were pooled using source data on the number of cases and denominators, rather than the prevalence estimates. More weight was given to the studies with a larger sample size in pooled estimates. No estimates were pooled among heterogeneous populations. The recalculation of the CIs using the conservative Fischer's exact method has standardised the data across estimates and improved transparency of calculation. Furthermore, no data from small sample studies was used.

5 Conclusions

This systematic literature review shows the diversity in the prevalence of chronic HBV and HCV infections. The availability of studies with relatively recent data on the prevalence in the general population is limited: data were available for slightly more than half of the 31 countries in the EU/EEA. For pregnant women and prisoners, studies were found for 40–50% of all EU/EEA countries. Data on the prevalence of HBV and HCV infections among MSM were lacking for most of the countries.

The lack of higher quality, recent, nationwide prevalence estimates, and the overall heterogeneity of the available studies makes it challenging to provide an EU/EEA overview of the current epidemiological situation of chronic viral hepatitis. Nevertheless, in this review, we were able to estimate the prevalence of HBV and HCV in the EU/EEA as a whole at around 1 percent, with an estimated total of 10.3 million HBV and HCV cases. More robust prevalence estimates are needed to gain further insights into the size of the populations with chronic hepatitis B or C infections, both with regard to the general population in the different EU/EEA countries and in specific risk groups. This information can then be used to better target primary and secondary prevention measures (e.g. screening and linkage to care of at-risk populations to identify patients with chronic hepatitis B and C who can benefit from new treatment options) and evaluate these measures.

Overall, countries in the eastern and southern part of the EU/EEA had a higher HBV and HCV prevalence than countries in the northern and western parts. Some countries with information based on general population studies, show evidence of a relatively low HBV/HCV prevalence in the general population, which stands in stark contrast with high prevalence in high-risk groups, mostly migrants, PWID, and prisoners. PWID remain at high risk for HCV infection, with high prevalence rates reported for most countries.

In all, prevalence in first-time blood donors was lower than that in the general population, while prevalence in pregnant women was slightly higher. The observed increase over time in the prevalence of chronic HBV in some countries indicates that it is important to maintain hepatitis B prevention and control high on the public health agenda.

Data on the prevalence of chronic viral hepatitis are unavailable for many countries; better surveillance and monitoring and further research are needed to provide reliable and comprehensive strategic information for policymakers who design and implement secondary prevention programmes for HBV and HCV infections in the EU/EEA. In the meantime, this report may provide a useful overview of what data are available with regard to screening and prevention programmes for those groups where the most benefits can be expected.

Annex 2. Prevalence of chronic HBV and HCV infections

Table A5. Prevalence of HBsAg in the general population, EU/EEA countries

Country	Author (year of publication)	Geographical coverage	Sampling period	Sampling method	Study population details	Age range	Sample size	Prevalence of HBsAg (95% CI)
Belgium*	Quoilin (2007) ⁽²³⁾	Regional	2002	Random	Region of Flanders	Standardised	Standardised	0.7% (0.5–0.8)
Belgium	Quoilin (2007) ⁽²³⁾	Regional	2002	Random	Region of Flanders	0 to >65	1,830	0.7% (0.4–1.2)
Belgium	Nardone (2009) ⁽²⁴⁾	N/R	2002–2003	Convenience	Residual lab samples representative of location and gender	1 to 15	1,175	0.7% (0.3–1.3)
Belgium	Nardone (2009) ⁽²⁴⁾	N/R	2002–2003	Convenience	Residual lab samples representative of location and gender	16 to 39	321	0.6% (0.1–2.2)
Croatia*	Vilibic-Cavlek (2014) ⁽²⁵⁾	Multi-centre	2010–2011	Convenience	Multi-centre study of patients attending a medical check-up. Covers 20% of regions	20 to 80	2,009	0.7% (0.4–1.2)
Croatia	Burek (2010) ⁽²⁶⁾	Multi-centre	2005–2007	N/R	Multi-centre study of staff in 20 prisons (10.9% of all prison staff)	N/R	259	2.3% (0.9–5.0)
Czech Republic*	Nardone (2009) ⁽²⁴⁾	N/R	2001	Random		Standardised	Standardised	0.6%
Czech Republic	Nardone (2009) ⁽²⁴⁾	N/R	2001	Random		16 to >40 years	1,669	0.4% (0.1–0.8)
Czech Republic	Nardone (2009) ⁽²⁴⁾	N/R	2001	Random		1 to 15 years	975	0.3% (0.1–0.9)
Czech Republic	Nardone (2009) ⁽²⁴⁾	N/R	2001	Random		16 to 39 years	1,148	0.2% (0.0–0.6)
Czech Republic	Nardone (2009) ⁽²⁴⁾	N/R	2001	Random		>40 years	521	0.8% (0.2–2.0)
France*	Meffre (2010) ⁽²⁷⁾	National	2004	Random	National sample obtained via primary health care insurance units	18 to 80	18,230	0.7% (0.5–0.9)
France	Bottero (2014) ⁽²⁸⁾	Multi-centre	2010–2011	Convenience	Multi-centre screening study in Paris region includes multiple risk groups such as migrants and PWID	Mean age 33	3,929	2.2% (1.7–2.7)
Germany [#]	Poethko-Müller (2013) ⁽²⁹⁾	National	2008–2011	Random	National coverage, DEGS1 study	18 to 79	7,047	0.3% (0.2–0.6)
Germany [#]	Huetter (2014) ⁽³⁰⁾	Local	2002	Random	Residents of Leutkirch, southern Germany	18 to 65, mean age 39.4	2,256	0.7% (0.4–1.1)
Germany	Wolffram (2015) ⁽³¹⁾	Regional	2012–2013	Convenience	Check-up 35+ attendees (mid-life health check) in North Rhine-Westphalia	Mean age 57.5	21,008	0.5% (0.4–0.6)
Germany*	Pooled	Pooled	2002; 2008–2011	Pooled	Pooled	Pooled	9,303	0.4% (0.3–0.5)
Greece*	Drositis (2013) ⁽³²⁾	Regional	2006–2010	Random	Adult residents of Arkalochori, a province in	Mean age 52	876	3.3% (2.2–4.7)

Country	Author (year of publication)	Geographical coverage	Sampling period	Sampling method	Study population details	Age range	Sample size	Prevalence of HBsAg (95% CI)
Greece	Dounias (2005) ⁽³³⁾	Local	1999–2001	Convenience	Municipal solid waste workers Crete	Mean age 42	159	7.5% (4.0–12.8)
Hungary*	Treso (2012) ⁽³⁴⁾	National	2007–2009	Convenience	Prison staff	21 to 60	1,066	0.4% (0.1–1.0)
Ireland*	Talento (2010) ⁽³⁵⁾	National	1992–2009	Exhaustive	Living and deceased solid organ donors	N/R	1,478	0.1% (0.0–0.4)
Ireland	Nardone (2009) ⁽²⁴⁾	N/R	2003	Convenience	Residual lab samples representative of location and gender	1 to 15	877	0.0% (0.0–0.9)
Ireland	Nardone (2009) ⁽²⁴⁾	N/R	2003	Convenience	Residual lab samples representative of location and gender	16 to >40	1,658	0.1% (0.0–0.4)
Ireland	Nardone (2009) ⁽²⁴⁾	N/R	2003	Convenience	Residual lab samples representative of location and gender	16 to 39	1,194	0.1% (0.0–0.5)
Ireland	Nardone (2009) ⁽²⁴⁾	N/R	2003	Convenience	Residual lab samples representative of location and gender	>40	464	0.2% (0.0–1.2)
Italy [#]	Cozzolongo (2009) ⁽³⁶⁾	Local	2005–2007	Random	GP records in Bari, Apuglia	18 to 93 Mean age 47	2,195	0.5% (0.3–1.0)
Italy [#]	Pendino (2005) ⁽³⁷⁾	Local	2002–2003	Random	Census data from Cittanova, Calabria	12 to 95	1,645	0.8% (0.4–1.3)
Italy [#]	Floreani (2006) ⁽³⁸⁾	Local	2001	Random	Residents of Arsita (Central Italy)	>8	142	0.7% (0.0–3.9)
Italy	Boccalini (2013) ⁽³⁹⁾	Regional	2009	Convenience	Residual blood samples from 0.05% of residents in Tuscany	1 to 50	1,071	2.0% (1.2–3.0)
Italy	Fabris (2008) ⁽⁴⁰⁾	Local	2002	Exhaustive	Vicenza, north-east Italy. A broken sewer pipe prompted HAV vaccination. Subjects were also tested for HBV/HCV	Mean age 42.1	965	1.0% (0.5–1.9)
Italy	Del Corno (2006) ⁽⁴¹⁾	Local	N/R	Random	Four towns in Isola Bergamasca (northern Italy)	20 to 70	2,829	5.8% (5.0–6.7)
Italy	Dazzani (2009) ⁽⁴²⁾	Local	2008	Convenience	Survey of residents in Bagnacavallo (Emilia-Romagna)	30 to 60	3,207	0.6% (0.4–1.0)
Italy	De Paschale (2012) ⁽⁴³⁾	Local	2007–2008	Convenience	Hospital lab samples from Legnano Hospital in northern Italy	Mean age 51.4	22,758	2.1% (2.0–2.3)

^a Various study designs and settings included

^b Samples with sample size under N = 10 were excluded

^c Calculated using the Fisher exact method for 95% CI

^d Study design: DT = diagnostic testing; SP = specific prevalence study (UAT = unlinked anonymous testing); RDS = respondent-driven sampling; SR = prevalence study based on self-reported test results

^e Setting: ANT = antenatal clinics; ARR = arrests; DEM = drug emergencies; DTC = drug treatment centres*; GPS = general practitioners; HTC = HIV testing centres; LTS = low-threshold services; NSP = needle exchanges; ODD = overdose deaths; OHC = other hospital or clinics; OTH = other; STI = STI clinics; STR = street; PHL = public health laboratories; PRI = prisons; IDUnk = IDU status not known**

^f Greece: two national estimates were pooled

* Having health problems is one selection criterion for admission to drug treatment in some countries or cities (Greece, Portugal, and Rome); due to long waiting lists or special programmes for infected IDUs, this may result in upward bias of prevalence.

** Data sources with no information on injecting status were excluded if possible because of the possible severe underestimation of prevalence in injectors.

Some of these data sources were included if samples were large or provided trends over time, in which case it is indicated that injecting status is unknown and that prevalence among injectors may be underestimated.

Table A16. Prevalence of anti-HCV in PWID, EU/EEA countries [17]

Annex 3. Country profiles

3.1 Austria

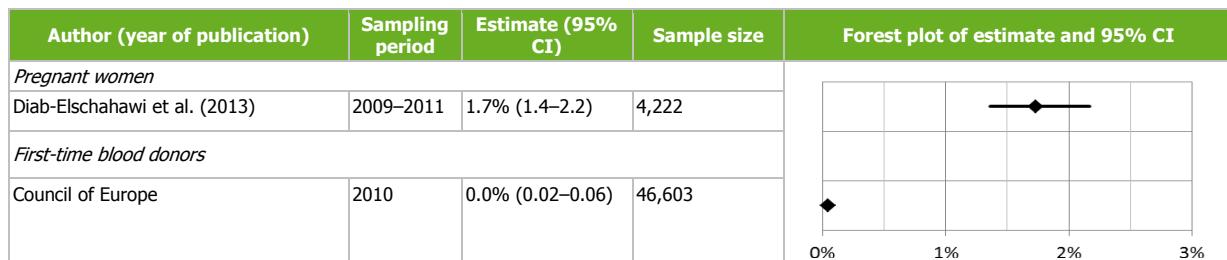

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Council of Europe	First-time blood donors	2010	N/A	46,603	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Diab-Elschahawi et al. (2013)	Pregnant women	2009–2011	1	4,222	Exhaustive	Universal antenatal screening at Vienna University Hospital	18 to 43
Council of Europe	First-time blood donors	2010	N/A	46,603	N/A	N/A	N/A

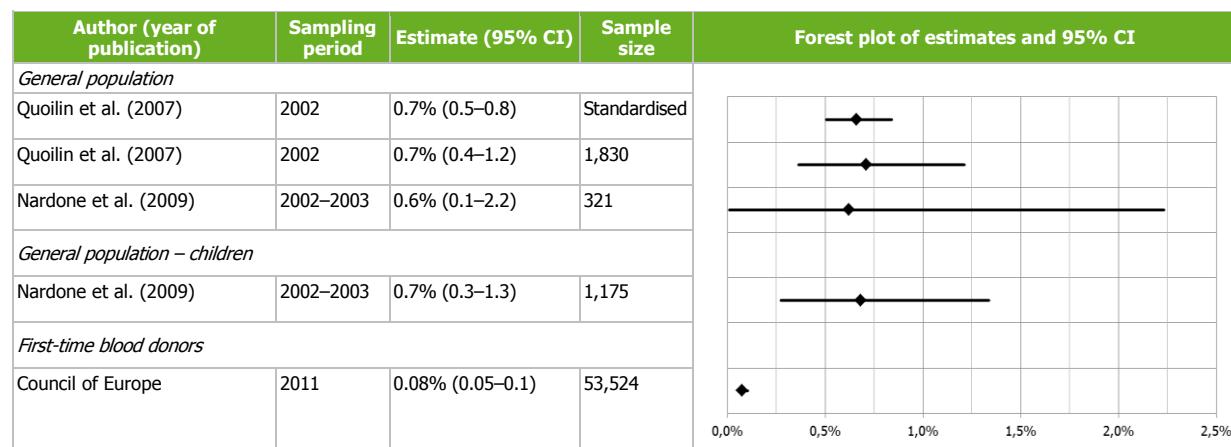

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimated prevalence range
EMCDDA	2013	HBsAg	Drug treatment, harm reduction and low-threshold services in Vienna. N=N/A	2.7% (no CI available)
EMCDDA	2013	Anti-HCV	Overdose deaths among current injectors. N=48	31.3% (18.7%–46.3%)

3.2 Belgium

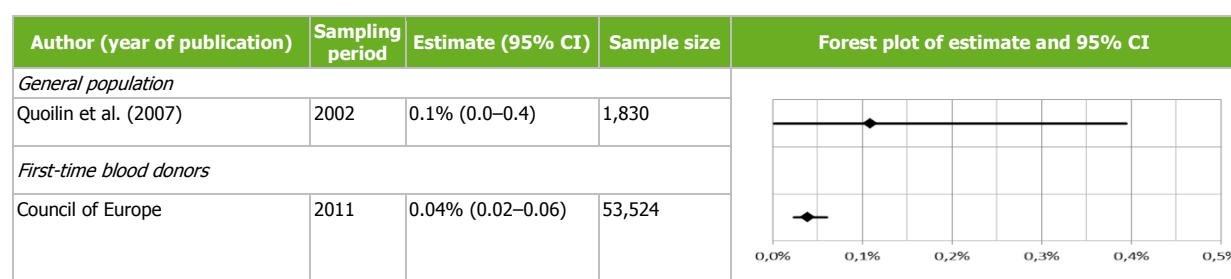

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Quoilin et al. (2007)	General population	2002	4	Standardised	Random	Region of Flanders	Standardised
Quoilin et al. (2007)	General population	2002	4	1,830	Random	Region of Flanders	0 to >65
Nardone et al. (2009)	General population	2002–2003	3	321	Convenience	Residual lab samples representative of location and gender	16 to 39
Nardone et al. (2009)	General population	2002–2003	3	1,175	Convenience	Residual lab samples representative of location and gender	1 to 15
Council of Europe	First-time blood donors	2011	N/A	53,524	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Quoilin et al. (2007)	General population	2002	4	1,830	Random	Region of Flanders	0 to >65
Council of Europe	First-time blood donors	2011	N/A	53,524	N/A	N/A	N/A

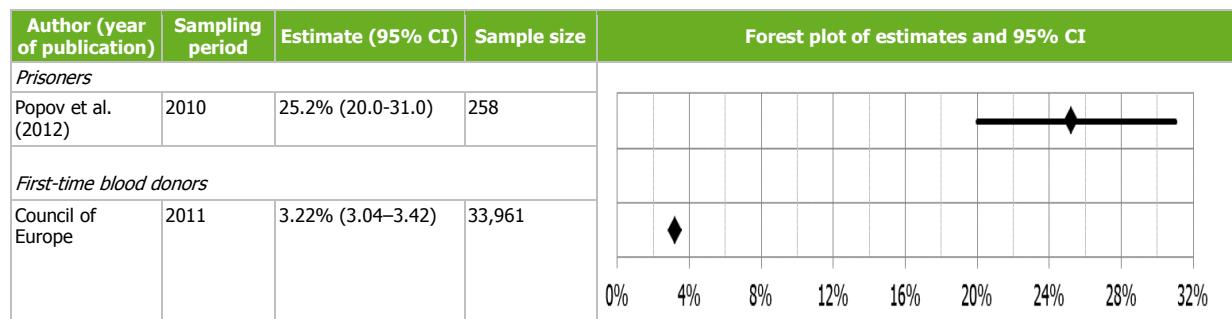

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimated prevalence range (no CI available)
EMCDDA	2013	HBsAg	Drug treatment services in Antwerp and the Flanders region. N=N/A	0.0% to 1.58%
EMCDDA	2013	Anti-HCV	Drug treatment and harm reduction services in Antwerp and the Flanders region. N=N/A	7.5% to 73.5%

3.3 Bulgaria

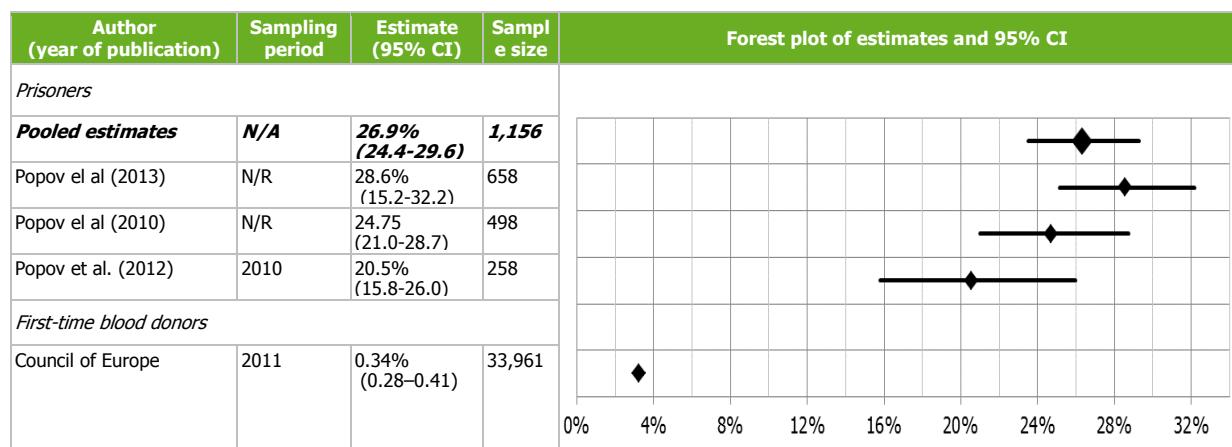

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Popov et al. (2012)	Prisoners (juveniles)	2010	3	258	Convenience	Study in two juvenile facilities	N/R
Council of Europe	First-time blood donors	2011	N/A	33,961	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
<i>Pooled estimates</i>	Prisoners	N/A	N/A	1,156	Pooled	Pooled	Pooled
Popov el al (2013)	Prisoners	N/R	5	658	Convenience	Four adult prisons and one juvenile facility	N/R
Popov el al (2010)	Prisoners	N/R	5	498	Convenience	Four adult prisons and one juvenile facility	N/R
Popov et al. (2012)	Prisoners	2010	3	258	Convenience	Study in two juvenile detention facilities	N/R
Council of Europe	First-time blood donors	2011	N/A	33,961	N/A	N/A	N/A

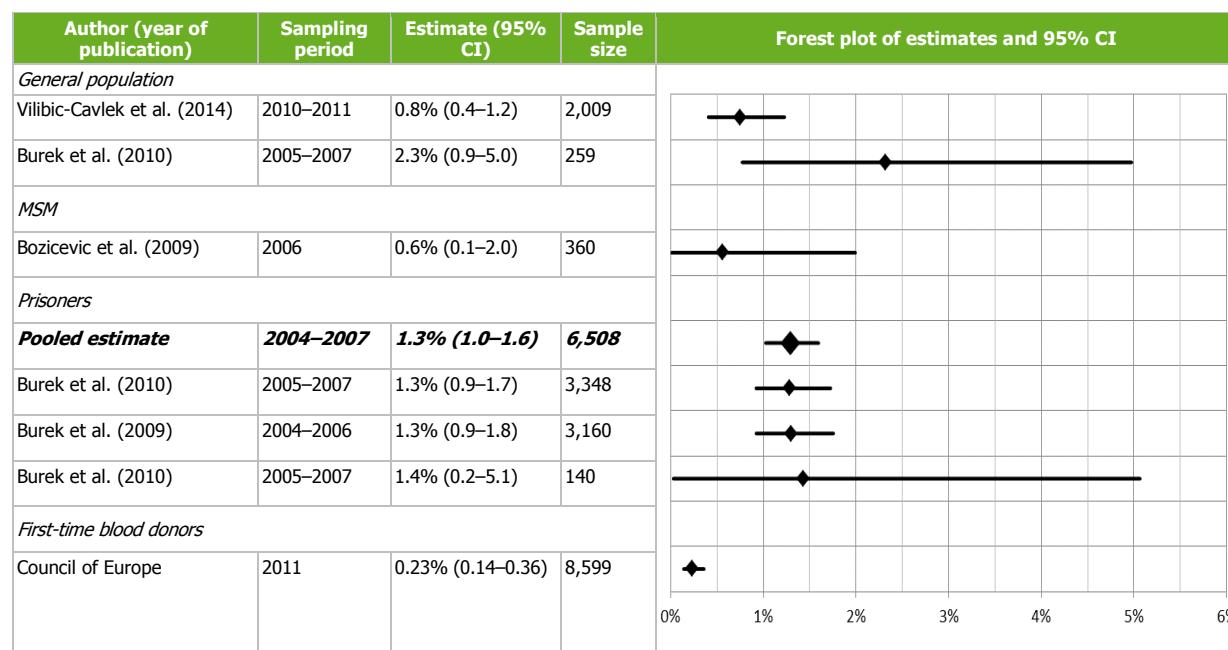

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (CI not available)
EMCDDA	2013	HBsAg	Street-based testing of ever injectors in Sofia. N=N/A	4.5%
EMCDDA	2013	Anti-HCV	Street-based testing of ever injectors in Sofia. N=N/A	62.7%

3.4 Croatia

HBsAg prevalence

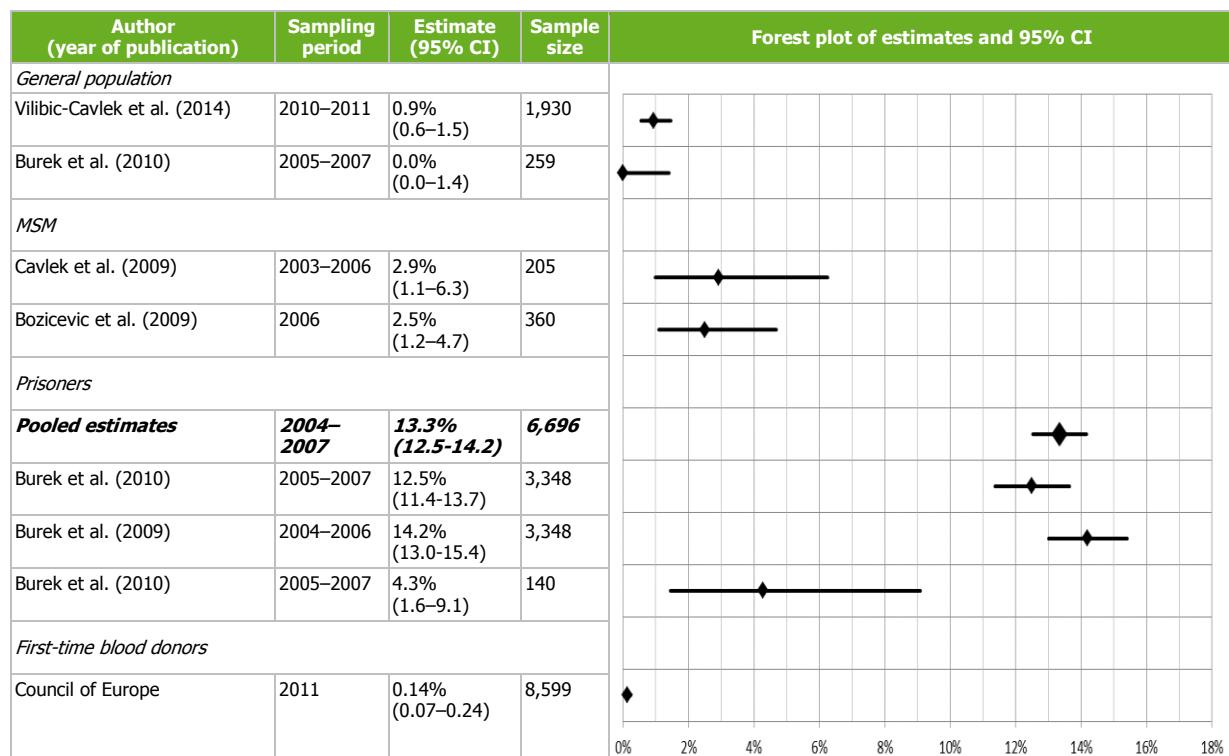

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Vilibic-Cavlek et al. (2014)	General population	2010–2011	4	2,009	Convenience	Multi-centre study of patients attending a check-up. Covers 20% of regions	20 to 80
Burek et al. (2010)	General population	2005–2007	3	259	N/R	Multi-centre study of staff in 20 prisons (10.9% of all prison staff)	N/R
Bozicevic et al. (2009)	MSM	2006	2	360	Respondent-driven	Zagreb	N/R
Pooled estimate	Prisoners	2004–2007	N/A	6,508	Pooled	Pooled	Pooled
Burek et al. (2010)	Prisoners	2005–2007	5	3,348	Convenience	Multi-centre study in 20 prisons. Sample includes PWID	32 to 70
Burek et al. (2009)	Prisoners	2004–2006	4	3,160	Convenience	Multi-centre study in 20 prisons. Sample of men only	N/R
Burek et al. (2010)	Prisoners	2005–2007	4	140	Convenience	Multi-centre study in 20 prisons. Sample includes PWID	16 to 18
Council of Europe	First-time blood donors	2011	N/A	8,599	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Vilibic-Cavlek et al. (2014)	General population	2010–2011	4	1,930	Convenience	Multi-centre study of patients attending a check-up. Covers 20% of regions	20 to 80
Burek et al. (2010)	General population	2005–2007	3	259	N/R	Multi-centre study of staff in 20 prisons (10.9% of all prison staff)	N/R
Cavlek et al. (2009)	MSM	2003–2006	2	205	N/R	Survey in seven cities	N/R

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Bozicevic et al. (2009)	MSM	2006	2	360	Respondent-driven	Zagreb	N/R
Pooled estimates	Prisoners	2004–2007	N/A	6,696	Pooled	Pooled	Pooled
Burek et al. (2010)	Prisoners	2005–2007	5	3,348	Convenience	Multi-centre study in 20 prisons. Sample includes PWID	32 to 70
Burek et al. (2009)	Prisoners	2004–2006	5	3,348	Convenience	Multi-centre study in 20 prisons. Sample includes men and women. 24% PWID	N/R
Burek et al. (2010)	Prisoners	2005–2007	4	140	Convenience	Multi-centre study in 20 prisons. Sample includes PWID	16 to 18
Council of Europe	First-time blood donors	2011	N/A	8,599	N/A	N/A	N/A

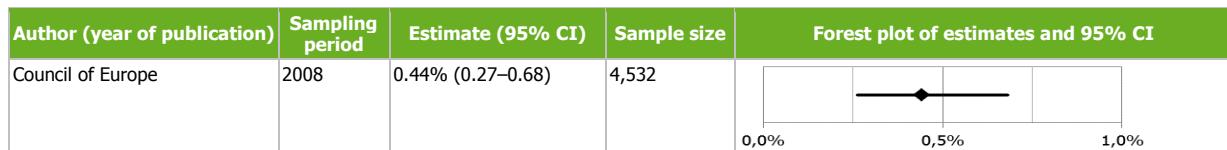

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (95% CI)
EMCDDA	2007	HBsAg	National sample of ever injectors from prisons. N=200	0.5% (0.0%–2.8%)
EMCDDA	2007	Anti-HCV	National sample of ever injectors from prisons. N=200	44.1% (37.0%–51.2%)

3.5 Cyprus

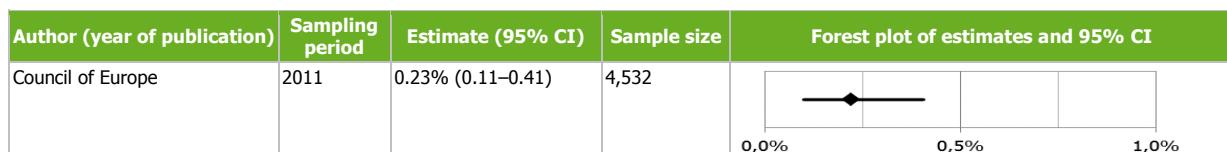

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Council of Europe	First-time blood donors	2008	N/A	4,532	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Council of Europe	First-time blood donors	2008	N/A	4,532	N/A	N/A	N/A

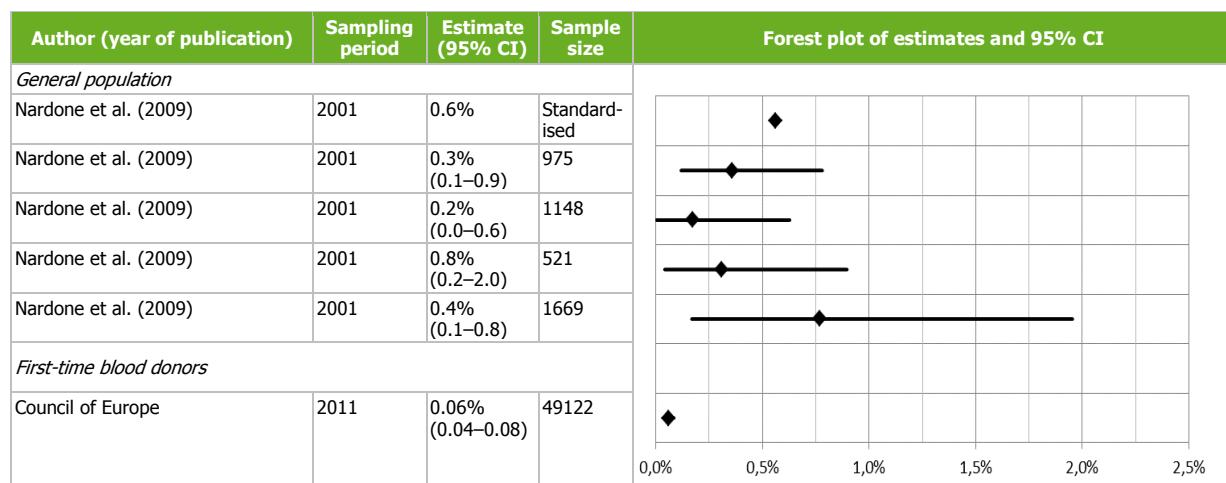

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (95% CI)
EMCDDA	2013	HBsAg	National sample of ever injectors from drug treatment services. N=82	6.1% (2.0%–13.7%)
EMCDDA	2013	Anti-HCV	National sample of ever injectors from drug treatment services. N=82	47.6% (36.4%–58.9%)

3.6 Czech Republic

HbsAg prevalence

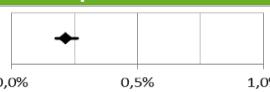

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Nardone et al. (2009)	General population	2001	4	Standardised	N/R	N/R	Standardised
Nardone et al. (2009)	General population	2001	4	975	Random	N/R	1 to 15
Nardone et al. (2009)	General population	2001	4	1148	Random	N/R	16 to 39
Nardone et al. (2009)	General population	2001	4	521	Random	N/R	>40
Nardone et al. (2009)	General population	2001	4	1669	Random	N/R	16 to >40
Council of Europe	First-time blood donors	2011	N/A	49122	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Council of Europe	First-time blood donors	2011	N/A	49122	N/A	N/A	N/A

HBsAg and anti-HCV prevalence: PWID

Author (year of publication)	Sampling period	Estimate (95% CI)	Sample size	Forest plot of estimates and 95% CI
Council of Europe	2011	0.22% (0.18–0.26)	49122	

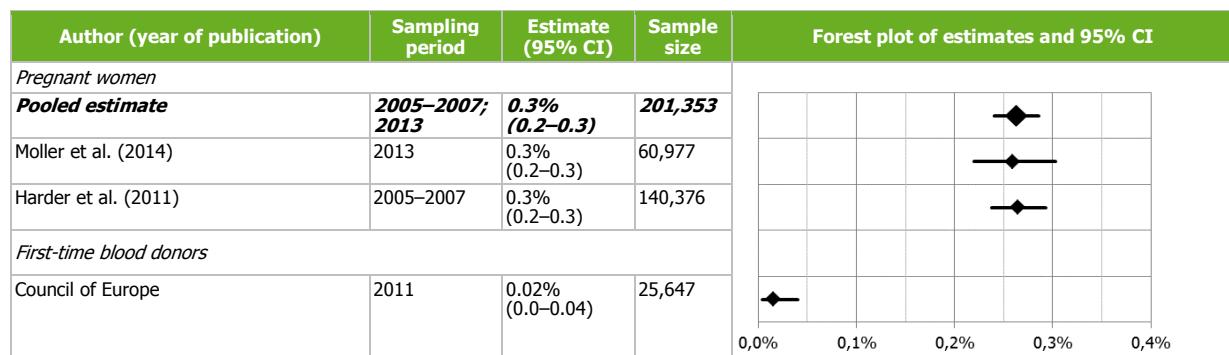

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (95% CI)
EMCDDA	2013	Anti-HCV	Needle exchanges, N=1,889	14.6% (13.1%–16.3%)

*No HBsAg prevalence data available

3.7 Denmark

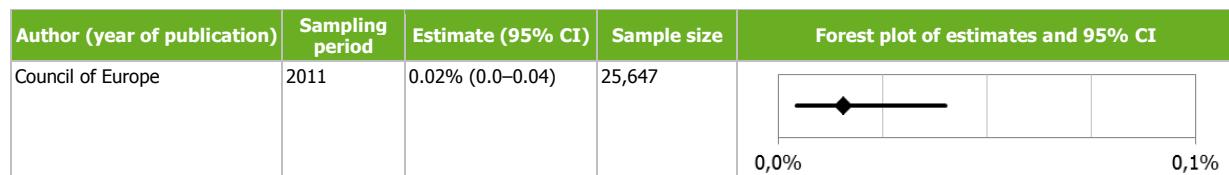

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Pooled estimate	Pregnant women	2005–2007; 2013	N/A	201,353	Pooled	Pooled	Pooled
Moller et al. (2014)	Pregnant women	2013	3	60,977	Exhaustive	National antenatal screening programme	N/R
Harder et al. (2011)	Pregnant women	2005–2007	3	140,376	Exhaustive	National antenatal screening programme	N/R
Council of Europe	First-time blood donors	2011	N/A	25,647	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Council of Europe	First-time blood donors	2011	N/A	25,647	N/A	N/A	N/A

HBsAg and anti-HCV prevalence: PWID

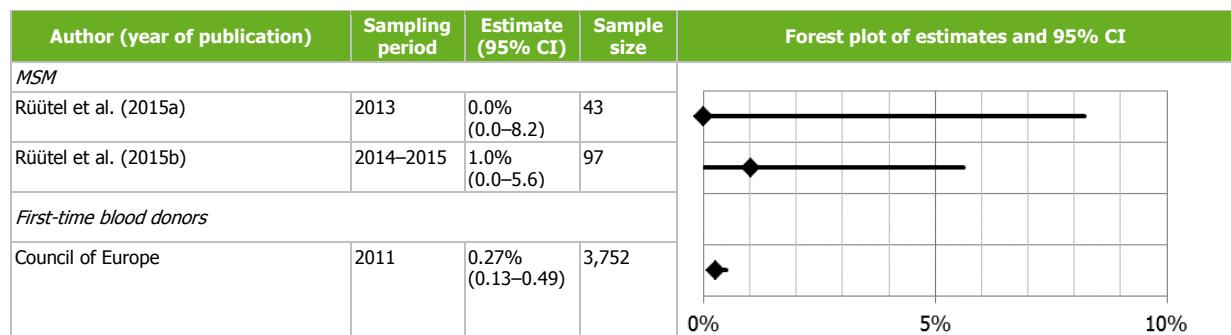

Source	Sampling period	Virological marker	Testing settings and sample size (if available)		Estimate (95% CI)
EMCDDA	2008	Anti-HCV	Overdose deaths (multi-site (N=3) study of post-mortem blood). N=223		52.5% (45.7%–59.2%)

*No HBsAg prevalence data available

3.8 Estonia

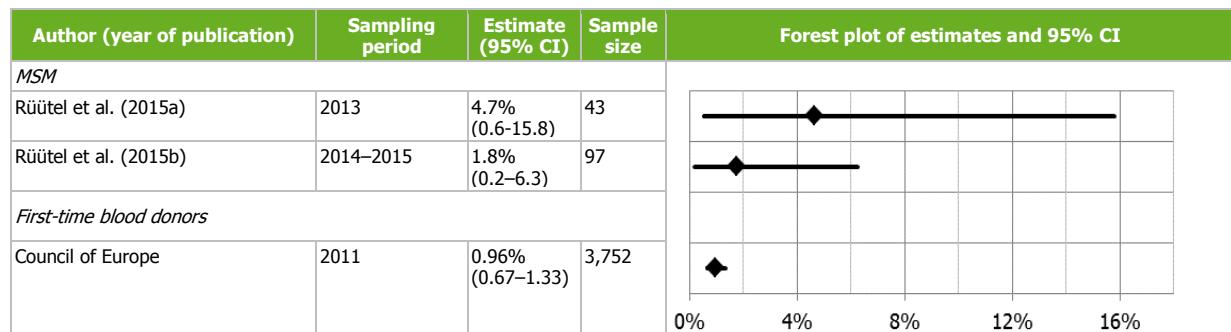

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Rüütel et al. (2015a)	MSM	2013	1	43	Convenience	Online survey with free, anonymous STI screening	18 to 67, mean age 33
Rüütel et al. (2015b)	MSM	2014–2015	1	97	Respondent-driven	Online survey with free, anonymous STI screening	14 to 68, mean age 30
Council of Europe	First-time blood donors	2011	N/A	3,752	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Rüütel et al. (2015a)	MSM	2013	1	43	Convenience	Online survey with free, anonymous STI screening	18 to 67, mean age 33
Rüütel et al. (2015b)	MSM	2014–2015	1	97	Respondent-driven	Online survey with free, anonymous STI screening	14 to 68, mean age 30
Council of Europe	First-time blood donors	2011	N/A	3,752	N/A	N/A	N/A

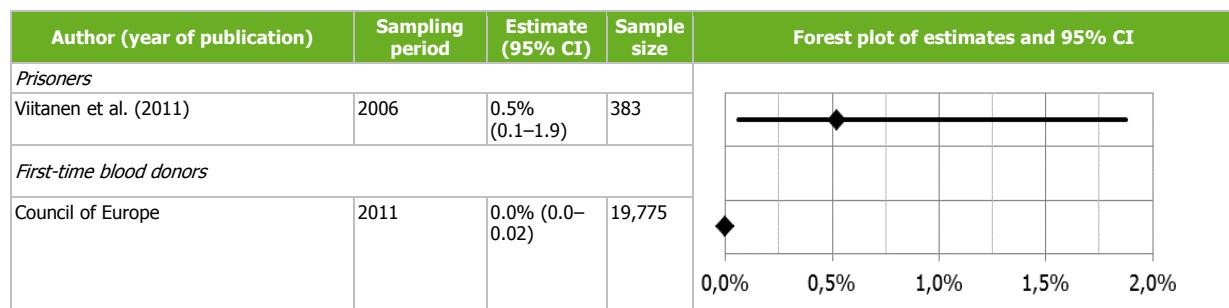

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (CI not available)
EMCDDA	2013	HBsAg	Single centre study of current injectors in a harm reduction service in Tallinn. N=N/A	4.0%
EMCDDA	2013	Anti-HCV	Single centre study of current injectors in a harm reduction service in Tallinn. N=N/A	90.2%

3.9 Finland

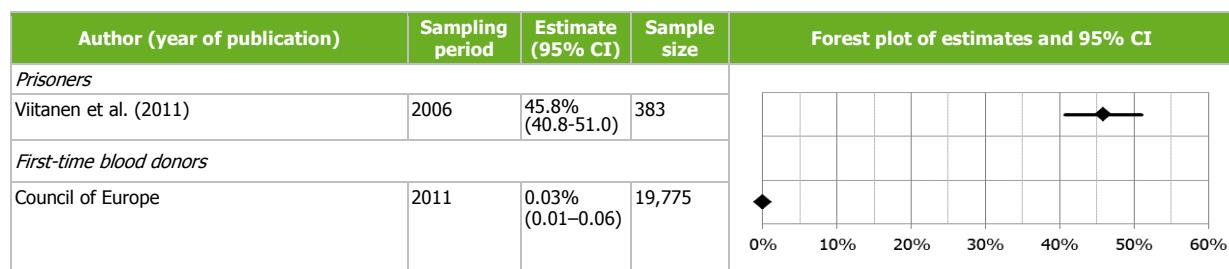

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Viitanen et al. (2011)	Prisoners	2006	6	383	Mixed methods	National coverage	16 to 69
Council of Europe	First-time blood donors	2011	N/A	19,775	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Viitanen et al. (2011)	Prisoners	2006	6	383	Mixed methods	National coverage	16 to 69
Council of Europe	First-time blood donors	2011	N/A	19,775	N/A	N/A	N/A

HBsAg and anti-HCV prevalence: PWID

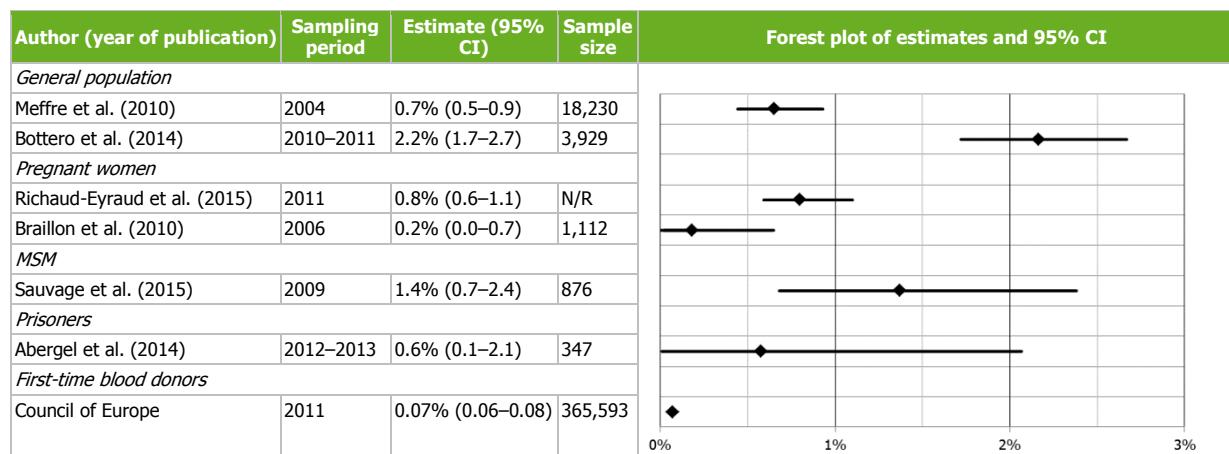

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (95% CI)
EMCDDA	2009	Anti-HCV	National (multi-centre, N=9) study in harm reduction services. Sample of current injectors. N=682	60.5% (56.8%–64.3%)

* No HBsAg prevalence data available

3.10 France

HbsAg prevalence

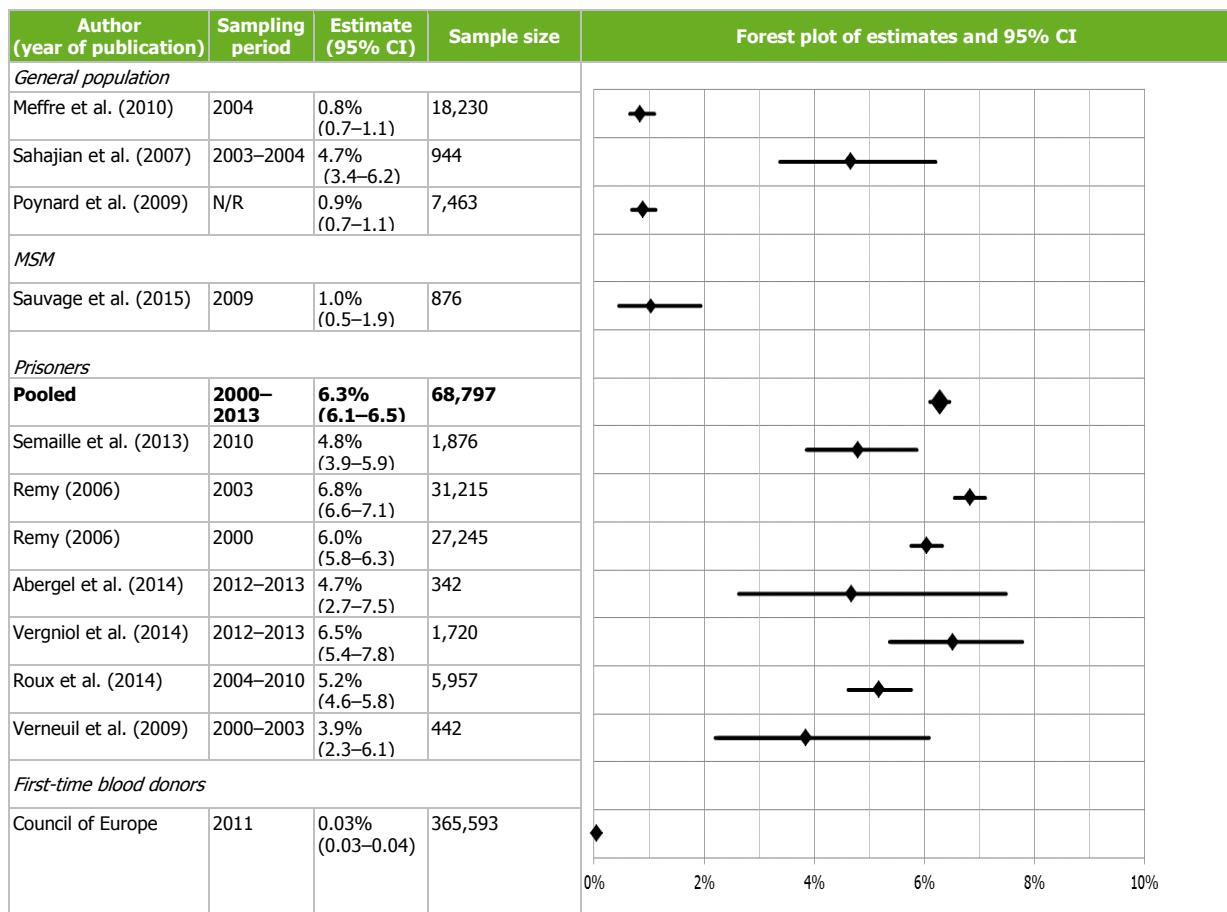

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Meffre et al. (2010)	General population	2004	4	18,230	Random	National sample obtained via primary health care insurance units	18 to 80
Bottero et al. (2014)	General population	2010–2011	3	3,929	Convenience	Multi-centre screening study in Paris region includes multiple risk groups such as migrants and PWID	Mean age 33
Richaud-Eyraud et al. (2015)	Pregnant women	2011	2	N/R	N/R	ELFE cohort study. National sample	25 to 34, mean age 30
Braillon et al. (2010)	Pregnant women	2006	1	1,112	Random	Regional coverage. Retrospective study design	Mean age 29
Sauvage et al. (2015)	MSM	2009	2	876	Convenience	Screening offered in 14 bars, saunas and 'backrooms'	>18
Abergel et al. (2014)	Prisoners	2012–2013	5	347	Exhaustive	Two <i>maisons d'arrêt</i> in Clermont-Ferrand and Riom. 97% male	25 to 39, mean age 30
Council of Europe	First-time blood donors	2011	N/A	365,593	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Meffre et al. (2010)	General population	2004	4	18,230	Random	National sample obtained via primary health care insurance units	18 to 80
Sahajian et al. (2007)	General population	2003–2004	3	944	Mixed	Underprivileged populations sampled via primary care services. Includes a small number of homeless people (n=89) and former/active PWID (n=16)	18 to >60
Poynard et al. (2009)	General population	N/R	2	7,463	Convenience	Attendees of social security health centres	>40
Sauvage et al. (2015)	MSM	2009	2	876	Convenience	Screening offered in 14 bars, saunas and 'backrooms'	>18
Pooled estimates	Prisoners	2000–2013	N/A	68,797	N/A	Pooled	Pooled
Semaille et al. (2013)	Prisoners	2010	6	1,876	Random	Stratified sampling by facility characteristics. Prisoners randomly sampled	18 to >50
Remy (2006)	Prisoners	2003	6	31,215	Other	Multi-centre study. Prisons asked to report screening practices, number of cases and capacity	N/R
Remy (2006)	Prisoners	2000	6	27,245	Other	Multi-centre study. Prisons asked to report screening practices, number of cases and capacity	N/R

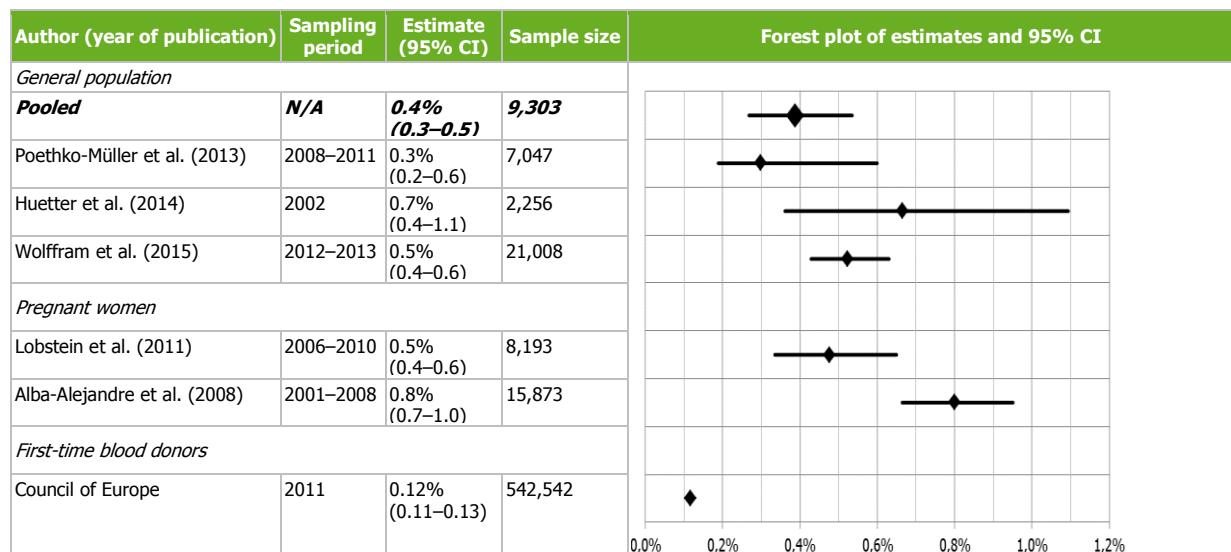

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Abergel et al. (2014)	Prisoners	2012–2013	5	342	Exhaustive	Two maisons d'arrêt in Clermont-Ferrand and Riom. 97% male	25 to 39, mean age 30
Vergniol et al. (2014)	Prisoners	2012–2013	4	1,720	Exhaustive	Multi-centre study involving all inmates. Unspecified facilities	N/R
Roux et al. (2014)	Prisoners	2004–2010	4	5,957	Convenience	Screening study. Testing offered due to multiple risk factors or on inmates request. 93% male	Mean age 28
Verneuil et al. (2009)	Prisoners	2000–2003	3	442	Random	Study in a remand centre in Caen	Mean age 29.7
Council of Europe	First-time blood donors	2011	N/A	365,593	N/A	N/A	N/A

3.11 Germany

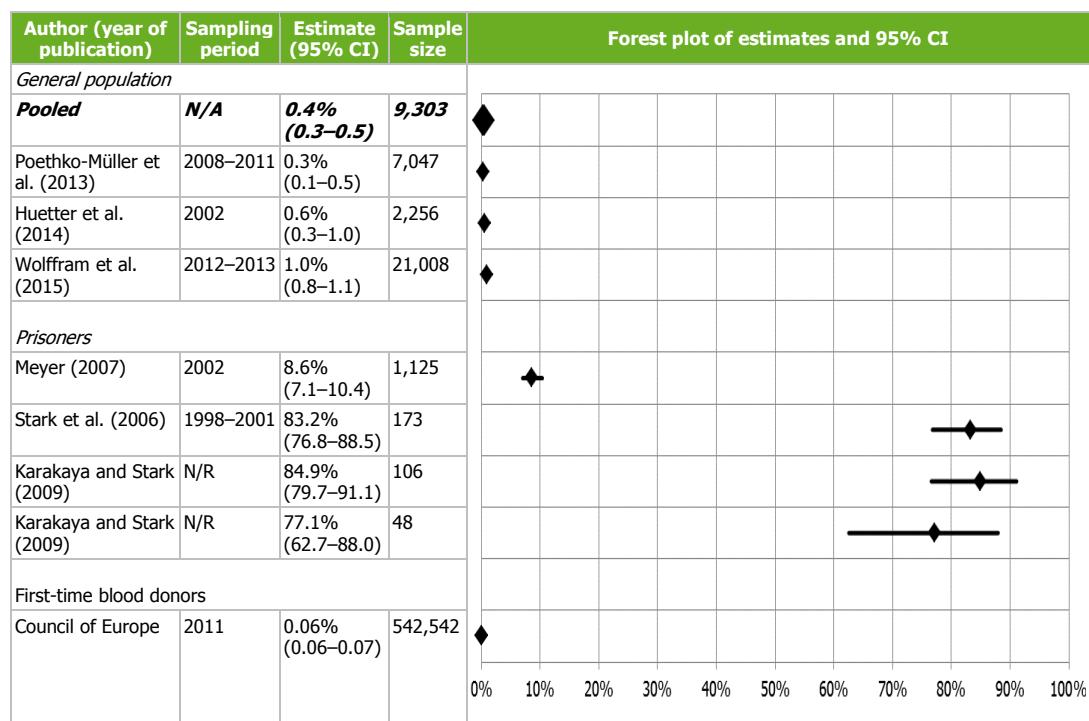

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Pooled estimates	General population	N/A	N/A	9,303	Pooled	Pooled	Pooled
Poethko-Müller et al. (2013)	General population	2008–2011	5	7,047	Random	National coverage. DEGS1 study	18 to 79
Huetter et al. (2014)	General population	2002	4	2,256	Random	Residents of Leutkirch, south Germany	18 to 65, mean 39.4
Wolffram et al. (2015)	General population	2012–2013	2	21,008	Convenience	'Check-up 35+' attendees (mid-life health check) in North Rhine-Westphalia	Mean age 57.5
Lobstein et al. (2011)	Pregnant women	2006–2010	1	8,193	Exhaustive	Deliveries in one hospital	N/R
Alba-Alejandre et al. (2008)	Pregnant women	2001–2008	1	15,873	Exhaustive	Antenatal screening in Leutkirch hospitals, south Germany	N/R
Council of Europe	First-time blood donors	2011	N/A	542,542	N/A	N/A	N/A

Anti-HCV prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Pooled estimates	General population	N/A	N/A	9,303	Pooled	Pooled	Pooled
Poethko-Müller et al. (2013)	General population	2008–2011	5	7,047	Random	National coverage. DEGS1 study	18 to 79
Huetter et al. (2014)	General population	2002	4	2,256	Random	Residents of Leutkirch, southern Germany	18 to 65, mean 39.4
Wolffram et al. (2015)	General population	2012–2013	2	21,008	Convenience	'Check-up 35+' attendees (mid-life health check) in North Rhine-Westphalia	Mean age 57.5
Meyer (2007)	Prisoners (juveniles)	2002	3	1,125	Exhaustive	Largest German juvenile prison. All new inmates offered screening	>16
Stark et al. (2006)	Prisoners	1998–2001	2	173	Exhaustive	Multi-centre study. All new inmates who had ever used illicit drugs (nasal or IV) offered screening	N/R
Karakaya and Stark (2009)	Prisoners	N/R	1	106	Convenience	Single prison study (Berlin). Females only, >90% PWID	22 to 47, mean age 31
Karakaya and Stark (2009)	Prisoners	N/R	1	48	Convenience	Single prison study (Berlin). Males only, >90% PWID	23 to 47, mean age 31
Council of Europe	First-time blood donors	2011	N/A	542,542	N/A	N/A	N/A

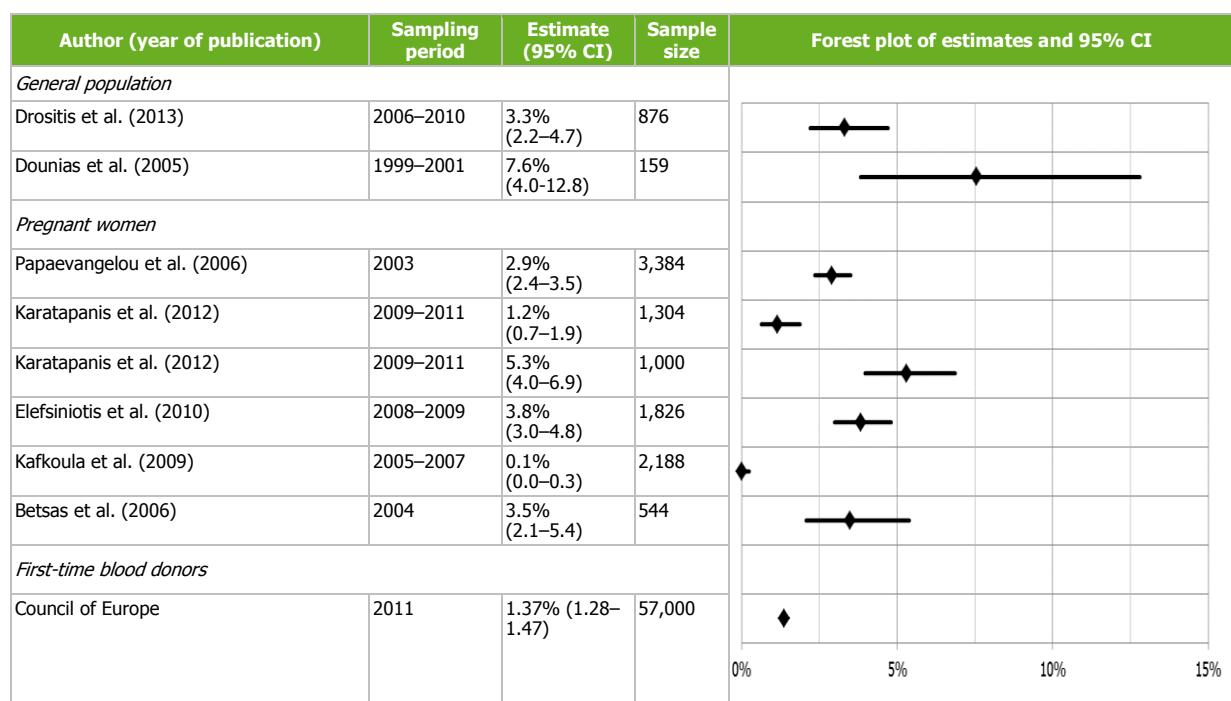

HBsAg and anti-HCV prevalence: PWID

Source	Sampling period	Virological marker	Testing settings and sample size (if available)	Estimate (CI not available)
EMCDDA	2011	HBsAg	Four low-threshold services in Berlin and Essen. Sample of current injectors. N=N/A	0.3% to 1.5%
EMCDDA	2011	Anti-HCV	Four low-threshold services in Berlin and Essen. Sample of current injectors. N=N/A	56.0% to 71.6%

3.12 Greece

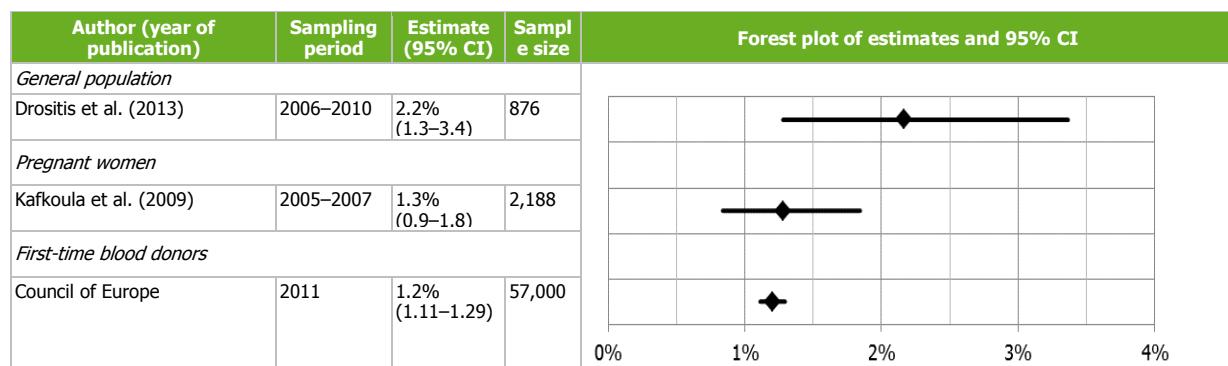

HbsAg prevalence

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range
Drositis et al. (2013)	General population	2006–2010	4	876	Random (87% response)	Adult residents of Arkalochori, Crete	Mean age 52
Dounias et al. (2005)	General population	1999–2001	1	159	Convenience	Municipal solid waste workers	Mean age 42
Papaevangelou et al. (2006)	Pregnant women	2003	3	3,384	Exhaustive	National antenatal screening programme	N/R
Karatapanis et al. (2012)	Pregnant women	2009–2011	1	1,304	Exhaustive	Antenatal screening attendees	Mean age 27.2
Karatapanis et al. (2012)	Pregnant women	2009–2011	1	1 000	Exhaustive	Antenatal screening non-attendees screened post-partum	Mean age 26.6
Elefsiniotis et al. (2010)	Pregnant women	2008–2009	1	1,826	Exhaustive	Consecutive women delivering at the Ob/Gyn dept.	N/R
Kafkoula et al. (2009)	Pregnant women	2005–2007	1	2,188	Exhaustive	Antenatal screening at Thriassio General Hospital	N/R
Betsas et al. (2006)	Pregnant women	2004	1	544	Exhaustive	Attendees of the University of Thessaloniki antenatal clinic	Mean age 32.3 (Greek-born); 27.1 (migrant)
Council of Europe	First-time blood donors	2011	N/A	57 000	N/A	N/A	N/A

Author (year of publication)	Population	Sampling period	Risk of bias score	Sample size	Sampling method	Sampling description	Age range

Annex 6. Data extraction

Table A20. Variables: data extraction

Variable	Description	Values
PMID	PubMed identifier, accession number	Numerical
Study ID	The ID links each study to the source article	Alphanumeric (PMID plus a, b, c.... for each study)
First author	Surname of first author of the article	
Year of publication	Year of publication of the article	Year: yyyy
Type of publication	Type of publication	Original article; review; report; abstract; commentary; erratum
Exclusion	If required, reason for exclusion	
Disease	Disease for which the study report prevalence estimates	HBV; HCV; both
Country	Country for which the study report prevalence estimates	Country name
Period of sampling	Year/s during which study sampling was conducted	Year: yyyy
Population coverage	Coverage of the population by the sampling design in geographic/demographic terms	National; regional; multicentre; single centre/local
Population	Target population sampled in the study	General population; pregnant women; MSM; prisoner
Study population details	Narrative field for any further relevant information on the study population	
Sampling approach	Description of sampling approach	Random sampling; convenience sampling; respondent-driven (i.e. snowballing); exhaustive (screening); not specified; other
Sample size	Total sample size (for all estimates)	Numerical
Response rate	Percentage of respondents	%
Type of sample	Description of sample type	Serum, saliva; dry blood spot
Type of test	Description of laboratory test used	HBsAg; HBV DNA; HBV rapid test; Anti-HCV; anti-HCV immunoblot; HCV RNA; HCV rapid test
Age group	Description of age group	0-17 (children); >17 (adults); all
Mean/median age	Mean or median age of study population	Numerical
Age range	Minimum and maximum age of study population	Numerical
Prevalence number per estimate	Number screened and number positive (HBsAg, HBV DNA, anti-HCV, HCV RNA)	Numerical
Prevalence % per estimate	Prevalence estimate (HBsAg, HBV DNA, anti-HCV, HCV)	%
95% CI per estimate	Calculated using Fisher method for 95% CI	%
Standardized	Weighted/standardized prevalence estimate available	Yes/No
Comments

HOW TO OBTAIN EU PUBLICATIONS

Free publications:

- one copy:
via EU Bookshop (<http://bookshop.europa.eu>);
- more than one copy or posters/maps:
from the European Union's representations (http://ec.europa.eu/represent_en.htm);
from the delegations in non-EU countries (http://eeas.europa.eu/delegations/index_en.htm);
by contacting the Europe Direct service (http://europa.eu/europedirect/index_en.htm) or
calling 00 800 6 7 8 9 10 11 (freephone number from anywhere in the EU) (*).

(*) The information given is free, as are most calls (though some operators, phone boxes or hotels may charge you).

Priced publications:

- via EU Bookshop (<http://bookshop.europa.eu>).
